## ABSTRACT

Plants harbor about 30 genes encoding major intrinsic proteins (*MIP*) which were named aquaporins because of the frequently observed water channel activity and their putative involvement in water relations. Plasma membrane intrinsic proteins (*PIP*) are subdivided into two groups with five *PIP1* and eight *PIP2* members in the model plant *Arabidopsis thaliana*. *PIP2* genes are highly homologous to each other, which might indicate a redundant function. However, several lines of evidence argue for gene-specific and non-redundant functions. *PIP2* genes exhibit overlapping, but differential expression patterns when assessed by promoter::GUS transgenic lines. Most *PIP2* genes were expressed in the region of the vascular tissue, however with differential cellular patterns. *PIP2;5* and *PIP2;7* were more uniformly found in leaves. *PIP2;4* was the only root-specific member and preferentially expressed in outer cell layers, whereas *PIP2;6* and *PIP2;8* were mostly found in young leaves with a distinct expression. PCA analyses based on publicly available stress-responsive expression patterns revealed distinct transcriptional responsiveness of *PIP2* genes. No visible phenotypes were observed for *pip2* knock-out lines under normal growth conditions. However, *pip2;3* mutants specifically showed salt-sensitivity, although the duplicated gene *PIP2;2* has only eight amino acids different from *PIP2;3* that mostly cluster in the region of the extracellular loop C. Transcriptional analysis using a custom-made DNA array focusing on membrane proteins indicated that loss-of-function of distinct *PIP2* genes did not interfere with major transport processes, at least at the transcriptional level. For several mutants of abundantly expressed *PIP2* isoforms, root transcriptome analysis was extended to the whole genome using Affymetrix ATH1 GeneChip. Furthermore, *PIP2* co-expression analyses revealed enrichment for different functional categories. Only *PIP2;1* and *PIP2;2* showed significant correlations with other *PIP* genes, however most *PIP2* genes were also correlated to *TIP* isoforms, suggesting an functional relationship of plasma membrane and tonoplast permeabilities. Surprisingly, at the protein level, the loss of *PIP2;1* or *PIP2;2* specifically provoked a decrease in *PIP1* proteins indicating a dependence of *PIP1* stability on these *PIP2* members.

So far, direct evidence for a participation of single *PIP* aquaporins in water transport *in planta* is scarce. To study non-invasively the impact of *PIP2* on water uptake, the kinetics of water translocation was analyzed by mass spectrometry of water extracted from *pip2;1* and *pip2;2* mutants grown in D-enriched medium. Retarded deuterium transfer into leaves of the single mutants indicated a direct involvement of both *PIP* proteins in water relations, whereas surprisingly the corresponding double mutant had compensated this slower uptake.

# 1 INTRODUCTION

## 1.1 Water uptake and transport across plant tissues

Water, often regarded as the “solvent of life”, is the single most abundant molecules in all cells and organisms and the maintenance of water status in suitable range is fundamental to life. In addition to the use of water in biochemical reactions and as a solvent, plants maintain their cellular turgor via sufficient water uptake. During development a plant can absorb water up to 500 times its fresh weight. However, only 2 to 5% of the water absorbed is retained by tissues for their growth, the remaining water is being lost by the leaves through evapotranspiration (Passioura, 1980). The passage of water through the whole plant is usually starting from the roots, the site of absorption, up to the aerial parts.

Water is first entering the roots due to water potential difference with the source water (e.g. soil, hydroponic medium) which is encompassing osmotic potential, pressure potential as well as gravity. The root is the fundamental organ for uptake and root water uptake in plants is related to processes such as transpiration and stomatal conductance, leaf water relations, leaf growth, and photosynthesis.

In the first place, to move into the roots, water has to flow radially across several cell layers (epidermis, cortex, endodermis and pericycle) to finally reach the vascular tissues constituting the xylem for long-distance transport (Fig. 1).

**Figure 1.** Schematic representation of the three different pathways involved in radial water transport across plant living tissues.

Three paths, for which relative contributions can vary depending upon growth conditions and species, co-exist for water transport across living tissues in plants (Fig. 1). The apoplastic path, i.e. within the extracellular cell wall space, is complemented by a cell-to-cell path,

which can be subdivided into the symplastic path through cytoplasmic continuities called plasmodesmata and the transcellular path across plasma and vacuolar membranes (Steudle, 2001). The latter is supposed to be important in root endodermis due to the presence of the hydrophobic deposits of the Casparian band, which obstruct the apoplastic path (not shown in Fig. 1). The composite transport model (Steudle, 1994; Steudle and Peterson, 1998) proposes that depending on the exact circumstances, the relative contribution of each water movement pathway to flow across the composite structure of tissues and organs in plants varies, which provide a useful mechanism by which the plant can respond to changing environmental conditions.

It is known that in case of low transpiration, for instance at night when stomata are closed, tension (negative hydrostatic pressure) generated by transpiration is considerably lower and therefore the cell to cell path governed by osmotic differences is favored. On the contrary, during transpiration, when stomata are open, water demand by the leaves leads to high tension exerted in the xylem, which will pull water up to aerial parts. Because of the low resistance of water flow exhibited by plant cell walls, water is mainly passing the apoplast in case of high transpiration.

Although the small and non-charged water molecule can cross membranes by simple diffusion, transmembrane path may be enhanced due to the high abundance of proteinaceous water channels (aquaporins, AQP) in biological membranes. Once water has reached the apoplastic region connected into vascular xylem tissue, water will flow axially through these vessels (Fig. 1 and 2). However, in the vascular tissues, apart from the uptake zone, radial exchange of water can also occur between surrounding cells (parenchyma cells) along the route (i.e. in hypocotyl and stem). This radial exchange between cells may also involve aquaporins (Fig. 2).

In the apoplastic xylem vessels, water transport occurs without penetrating lipid bilayer membranes. Xylem vessels are made up of dead cells that have lost their protoplasts and oppose a negligible resistance to water flow and thus, allow the bulk flow of water.

In the aerial organs, water arrives from the xylem vessels and hence it will be distributed in the apoplastic space following the water potential gradient. From there, it can enter mesophyll and epidermal cells of a leaf (Fig. 2). Within that compartment it may also be redistributed. In addition, part of the water may also circulate back to the root from the aerial part via a second long-distance transport system, the phloem (Fig. 2). Xylem tissues take part in the conduction of minerals, while the living, connected tissue of phloem cells is involved in metabolite transport along with water. On the contrary to water flow in xylem tissues, phloem loading

needs membrane transport potentially involving aquaporins. However, depending on the environmental conditions the major part of the water taken up by the roots may be lost by transpiration to the atmosphere. Transpiration is mainly occurring via the stomata, but may not be completely prevented by cuticular waxes on the epidermal surface as well (Riederer, 2006). Importantly, the diffusion through stomata is not unidirectional, but it also allows the diffusion of gases including CO<sub>2</sub> and H<sub>2</sub>O into the leaf. Thereby, plants can also absorb water from the atmosphere. The amount of water lost by a plant through transpiration is primarily related to stomata aperture and on the water potential difference between atmosphere and leaf internal spaces, which is also influenced by physiological parameters such as leaf size, size and surface properties of leaf air spaces, and water supply via vascular tissues. The atmosphere's water potential is governed by environmental parameters like humidity, temperature, and wind.

As a summary, water transport across living tissues represents the critical parameter, due to the stronger resistance, for water uptake by root and redistribution to the surrounding cells and in aerial parts. Therefore, the presence of aquaporins in cellular membrane is supposed to play an important role in these processes.

**Figure 2. Schematic representation of whole plant water transport within and between tissues.** Arrows indicate flow of water with different thickness related to putative transport capacity. Stippled arrows refer to apoplastic path, whereas solid arrows relate to paths possibly involving aquaporins. In case of deuterium enriched water (see below, Results 3.7)  $R$  is the molar ratio of the heavy (D) and light isotope (H) in the respective compartments. Red: D enriched water. Black arrow indicates low isotopic ambient water.

## 1.2 Aquaporin water channels

### 1.2.1 History and discovery of aquaporins

The organization of water within biological compartments is fundamental to life. Water can move through the membrane simply by diffusion through the lipid bilayer. However, the discovery of aquaporins brought the new view that, in addition, a set of proteins exists that enhance water permeability of biological membranes.

Historically, red cells' membrane has been a key system for the molecular characterization of water channels, because erythrocytes exhibited a 10- to 20-fold increased water permeability that cannot be explained by the facile diffusion of water through lipid bilayer membranes (Dainty and Ginzburg, 1963; Macey, 1984; Finkelstein, 1987; Schäffner, 1998). Several researchers suggested the participation of a proteinaceous agent in water permeability (Macey, 1984; Benga et al., 1986; Wayne and Tazawa, 1990), but none of them could identify the nature of the protein. Eventually, CHIP28, a Channel-forming Integral Protein of 28 kDa was first characterized as a contaminant of the rhesus factor (Agre et al., 1987). It had been never considered with respect to water-channel activity, because it was hardly detected on stained gels, although later it turned out to be very abundant in the red cell membranes. The discovery that this protein is also abundantly expressed in renal tubules, which show a high hydraulic permeability as well, lead to the hypothesis that **CHIP28 could be a water channel** (Preston and Agre, 1991). The water channel hypothesis was then confirmed by heterologous expression of this protein in *Xenopus* oocytes, which lead to a high water permeability of the oocyte membrane (Preston et al., 1992). CHIP28 was later renamed AQP1 (aquaporin1). AQP1/CHIP28 showed homology to the Major Intrinsic Protein (MIP) in the membrane of mammalian eye lens fiber cells, which is now, designated AQP0. The gene family was therefore generally named MIP family and is now known to be a large family of related proteins.

Representatives of the family have been found in all kingdoms, and, currently, more than 200 members of the aquaporin family have been found in bacteria, plants, fungi, animals and humans; the physiological and pathological implications are being uncovered. For instance, in vertebrates, combined efforts of several laboratories have led to the molecular identification of 11 to 13 aquaporin homologues clustered in two subsets referred to as aquaporins (AQP0-2, 4-6, 8, 11 and 12) and aquaglyceroporin (AQP 3, 7, 9 and 10) since they are permeated by water and/or glycerol. *Escherichia coli* has one member of each subset, AqpZ and GlpF (Zardoya, 2005). In the model plant *Arabidopsis thaliana*, 35 isoforms have been identified (Johanson et al., 2001; Quigley et al., 2002).

### 1.2.2 Classification of the plant MIP superfamily of proteins

Due to the fact that most plants are immobile, a rapid response of physiological processes to environmental conditions is essential for their survival. Thus, in comparison to many other organisms, plants might need a more sophisticated tuning of water balance, which might be reflected by the comparably large amount of aquaporin genes in plant genomes. In *Arabidopsis*, 35 isoforms, spread over all 5 chromosomes, have been found (Johanson et al., 2001; Quigley et al., 2002), while 36 and 33 aquaporin isoforms have been identified in maize and rice, respectively (Chaumont et al., 2001; Sakurai et al., 2005). According to sequence homologies the plant MIP family has been classified into four clades, which to some extent correspond to their sub-cellular localizations, the PIPs (Plasma membrane Intrinsic Proteins), the TIPs (Tonoplast Intrinsic Proteins), the NIPs (Nod26-like Intrinsic Proteins) and the SIPs (Small basic Intrinsic Proteins) (Chaumont et al., 2001; Johanson et al., 2001; Quigley et al., 2002) (Fig. 3).

The PIP proteins, the largest plant aquaporin subfamily, are divided into two subgroups, PIP1 and PIP2 (Chaumont et al., 2000; Johanson et al., 2001). *Arabidopsis* harbors five PIP1 and eight PIP2 members. All plant PIP2 proteins examined have been shown to have high water channel activity when tested in heterologous system (e.g. *Xenopus* oocytes), whereas PIP1 proteins often are inactive or have lower activity (Daniels et al., 1994; Kammerloher et al., 1994; Yamada et al., 1995; Weig et al., 1997; Johansson et al., 1998; Biela et al., 1999; Dean et al., 1999; Chaumont et al., 2000; Marin-Olivier et al., 2000; Dixit et al., 2001; Moshelion et al., 2002; Fetter et al., 2004; Temmei et al., 2005).

TIP proteins with 10 members in *Arabidopsis* are expressed in vacuolar membranes and may represent, together with the PIPs, central pathways for transcellular and intracellular water transport (Maurel et al., 2002).

A third clade, NIP, encompasses nine members that are close homologues to soybean Nodulin 26 (Nod26), an abundant major integral protein of symbiosome membrane of nitrogen fixing root organ called nodule. Nod26 has been classified into the MIP superfamily and describes the archetype of the subfamily (Sandal and Marcker, 1988). Consequently, all proteins related to nodulin26-like intrinsic proteins were named NIP.

SIP proteins, the smallest subfamily, comprise three members which were recently identified by database mining and phylogenetic analysis (Johanson and Gustavsson, 2002). They are the most divergent aquaporins in plants and show a high level of diversity even within the subfamily. Although their transport specificity and physiological functions remain to be elucidated, SIP1;1 and SIP1;2 were recently characterized as water channels by heterologous

expression in yeast, whereas SIP2;1 showed no water channel activity. In addition, transient expression of *Arabidopsis* SIP proteins fused to GFP demonstrated these proteins to be mostly detected in the endoplasmic reticulum (ER) (Ishikawa et al., 2005).

Figure 3. Phylogenetic tree of the 35 MIP proteins in *Arabidopsis thaliana* and their grouping in four subfamilies.

### 1.2.3 Structural features of aquaporins and transport selectivity

#### 1.2.3.1 Common structural features of aquaporins

Aquaporins are small (23-34 kDa) transmembrane proteins that contain six membrane-spanning helices and 5 loops (loops A to E) with N- and C-termini residing in the cytosol (Jung et al., 1994) (Fig. 4a). Loops A and C are extracellular and loop D is intracellular. Loops B and E fold back into the membrane from the inner (B) and the extracellular (E) sides forming two short half helices penetrating the membrane as a seventh helix. They contain the highly conserved duplicated asparagine-proline-alanine (NPA) signature motif (Fig. 4a). Structural investigations and simulations elucidated that the seventh transmembrane domain is intimately involved in creating an aqueous pathway through the protein (Jung et al., 1994; Murata et al., 2000; Sui et al., 2001). The pore narrows to approximately 3 Å in diameter, which constraints the transport of large uncharged molecules through aquaporin; the pore is just large enough to accommodate a single water molecule.

**Figure 4. Hourglass model of AQP showing its membrane topology.**

(a) Schematic representation of an AQP. Six transmembrane alpha helices (1 to 6) are connected by five loops (A to E). With folding of loop B and E the two helical domains containing the conserved NPA motifs overlap within the lipid bilayer to form a single aqueous pathway. (b) Molecular structure of the closed conformation of spinach *SoPIP2;1* showing the conserved tetrameric structure of aquaporins (Protein Data Bank code 1Z98). Each subunit defines its own pore surrounding a fifth pore in the center of the tetramer.

Three-dimensional structure analyses of archaeal AqpM (Lee et al., 2005), bacterial AqpZ (Ringler et al., 1999; Savage et al., 2003), mammalian AQP0, 1, 2 and 4 (Murata et al., 2000; Sui et al., 2001; Gonen et al., 2004; Schenk et al., 2005; Hiroaki et al., 2006), and recently the spinach *SoPIP2;1* (Kukulski et al., 2005; Törnroth-Horsefield et al., 2006) have shown that AQPs share typical but conserved structural properties. They form tetramers in the membrane with each subunit defining its own pore. The four subunits are arranged in parallel, forming a fifth pore in the center of the tetramer (Fig. 4b). The conductance of ions ( $K^+$ ,  $Cs^+$ ,  $Na^+$  and tetramethylammonium) through the central pore of the human AQP1 tetramer had been reported (Saparov et al., 2001; Yool and Weinstein, 2002), but this property could not be reproduced by others.

In plants, aquaporin structure has been observed by cryo-electron microscopy of 2D crystals of bean *PvTIP3;1* (Daniels et al., 1999) and spinach *SoPIP2;1* (Fotiadis et al., 2001; Kukulski et al., 2005). *SoPIP2;1* is the only plant aquaporin for which an atomic resolution at 2.1 Å based on X-ray crystallography is available (Törnroth-Horsefield et al., 2006).

### 1.2.3.2 Water transport selectivity

The movement of water through aquaporin is driven by osmotic or pressure gradients, i.e. aquaporins are not pumps or transporters. They form a simple pore that allows a bidirectional flow of water across membranes due to water potential differences. The permeability has been measured to be around  $3 \times 10^9$  water molecules per subunit per second with a low Arrhenius activation energy ( $<20 \text{ kJ mol}^{-1}$ ), which is close to the activation energy for water diffusion. Importantly, the permeability is selective since water ( $\text{H}_2\text{O}$ ) passes through the membranes with almost no resistance, while oxonium ions ( $\text{H}_3\text{O}^+$ ) are completely excluded from the pores. Furthermore, migration of  $\text{H}^+$  via hydrogen bonding is also prevented. The resolution of the bacterial aquaglyceroporin GlpF and of mammals AQP1 structures by X-ray crystallography has enabled molecular dynamics simulations, which led to the understanding of the mechanism how aquaporins transport water and exclude proton movement (Fu et al., 2000; de Groot and Grubmüller, 2001; Sui et al., 2001). At the narrow center of the pore, the highly conserved Asn76 and Asn192 in the NPA motif of loop B and E are juxtaposed (Fig. 4a). Except the two Asn residues the constraint points are hydrophobic. Therefore, the interaction of the oxygen atom of water molecules from a single file with these Asn residues reorients the two hydrogen atoms when water passes through this constraint. The formation of hydrogen bonds with adjacent water molecules is thus prevented, contributing to the exclusion of proton-permeation through hydrogen bonds. In addition, a second narrower constriction point, named aromatic/Arg (Ar/R) region is formed towards the extracellular part, above the NPA region. In AQP1, the Ar/R region is constituted of aromatic residues Phe58, His182, Cys191 and Arg197. This tetrad, due to steric effects, functions as a selectivity filter, which permits the flux of water, but excludes bigger solutes. In fact, Arg197 residue forms a positive charge acting as a site for electrostatic repulsion of protons. At low pH, His182 on the other wall becomes protonated and forms a partial positive charge. The positive charges of Arg197 and His 182 provide a strong repelling charge against the passage of protons during water permeation (Fujiyoshi et al., 2002). Thus, by combining an aromatic/R-region and the NPA motives aquaporins possess a two-stage filter.

Plant aquaporin water permeability has mostly been shown by heterologous expression in *Xenopus* oocytes or yeast. The vacuolar TIP1;1 (initially named  $\gamma$ -TIP) from *Arabidopsis thaliana* was the first plant MIP member that showed water transport activity when assayed by heterologous expression in *Xenopus* oocytes (Maurel et al., 1993). Later homologues of *Arabidopsis* residing in plasma membrane were characterized (Daniels et al., 1994; Kammerloher et al., 1994; Weig et al., 1997). Since then, MIPs from a broad range of species

tested for water transport activity have been found to be water channels, such as from maize (Barrieu et al., 1998; Chaumont et al., 1998), wheat (Niemietz and Tyerman, 1997), rice (Lian et al., 2004), tomato (Werner et al., 2001), barley (Katsuhara et al., 2002), tobacco (Fray et al., 1994; Maurel et al., 1997), potato (Heymann and Engel, 1999), ice plant (Yamada and Bohnert, 2000), sunflower (Sarda et al., 1997), cauliflower (Reisen et al., 2003), radish (Higuchi et al., 1998; Suga et al., 2001), olive (Secchi et al., 2007) or *Panax ginseng* (Lin et al., 2007).

### 1.2.3.3 Additional transport specificities

Besides water, additional permeabilities have been shown for various aquaporin isoforms of all subclasses of plant aquaporins. Indeed, it has become evident that some aquaporins do not have strict water permeability and may transport other molecules. Most evidences for AQP permeability come from heterologous expression in *Xenopus* oocyte or yeast, or after reconstitution in proteoliposomes but studies *in planta* are rare (see below). Thus, besides water, some plant aquaporins have also been shown to transport glycerol, urea, formamide (Rivers et al., 1997; Whittembury et al., 1997; Dean et al., 1999; Gerbeau et al., 1999) or other small, uncharged molecules like boric acid (Dordas et al., 2000).

Heterologous expression in yeast of *Arabidopsis* NIPs (*AtNIP1;1*, *AtNIP1;2*) indicated that they formed functional glycerol permeases and exhibited low water conductivity (Weig et al., 1997; Weig and Jakob, 2000; Wallace et al., 2002).

New evidences that aquaporins can transport additional physiologically important molecules have recently been presented. For instance, recent studies suggested participation of TIPs to transport ammonium  $\text{NH}_4^+$  and ammonia  $\text{NH}_3$  from the cytoplasm into the vacuole. TIPs of *Arabidopsis* (Loque et al., 2005) and wheat (Jahn et al., 2004; Holm et al., 2005) could be identified in yeast complementation assays that conferred permeability to ammonium as well as to methylammonium or to formamide. Expression of *AtTIPs*, several mammalian aquaporins (AQP1, 3, 8 and 9) or wheat TIP2;1 in *Xenopus* oocytes showed an increased permeability for  $\text{NH}_4^+/\text{NH}_3$  (Holm et al., 2005; Loque et al., 2005). Consequently, TIPs could be involved in the detoxification of ammonia from the cytoplasm by an acid-trap mechanism as suggested by Loque et al. (2005).  $\text{NH}_3$  was transported into the acidic vacuolar lumen, where it binds a proton to form  $\text{NH}_4^+$ . However, transgenic *Arabidopsis* plants overexpressing *AtTIP2;1* showed no differences in capacity and rate of ammonium accumulation in root cells compared to wild-type plants. Hence, the physiological consequences of TIP mediated  $\text{NH}_3$  transport are still unknown (Loque et al., 2005). A contribution for  $\text{NH}_3$  permeation has also

been considered for the NIP soybean Nod26 (Niemietz and Tyerman, 2000; Wallace et al., 2006).

Although it has been previously suggested, the first molecular genetic evidence for the diffusion of hydrogen peroxide through aquaporin has been presented only recently. In this study, among 24 aquaporins from plants and mammals tested, human AQP8 as well as *Arabidopsis* TIP1;1 and TIP1;2 showed hydrogen peroxide permeability (Bienert et al., 2007). Various studies have also demonstrated that essential nutrient may permeate through aquaporin. Thus, evidence for boric acid uptake has been shown for the *Arabidopsis* NIP5;1 (Takano et al., 2006) while heterologous expression of rice *Lsi1* in oocytes has shown transport activity for orthosilicic acid (Ma et al., 2006). In rice, the *Lsi1* gene is constitutively expressed in roots and has been shown to belong to the NIP subfamily; its closest homologue in *Arabidopsis* is *AtNIP7;1*.

Eventually, one of the most fascinating proposals for aquaporin permeability is certainly CO<sub>2</sub> transport. Indeed, CO<sub>2</sub> permeability has been suggested for mammalian aquaporins as well as tobacco *NtAQP1* (Cooper and Boron, 1998; Nakhoul et al., 1998; Prasad et al., 1998; Cooper et al., 2002; Uehlein et al., 2003). The PIP1 member *NtAQP1* was shown to increase membrane permeability to CO<sub>2</sub> in *Xenopus* oocytes (Uehlein et al., 2003). CO<sub>2</sub> transport mediated by PIP2 aquaporins has been suggested for the barley aquaporin *HvPIP2;1* when overexpressed in rice. The level of *HvPIP2;1* was found to be strongly related to mesophyll conductance and the results were interpreted in a way that *HvPIP2;1* has a role in CO<sub>2</sub> diffusion in rice leaves (Hanba et al., 2004). However in this study molecular characterization in the oocyte system was not provided. Consequently, compelling evidences for aquaporin-mediated CO<sub>2</sub> transport *in planta* are still missing although promising evidence for the *in vivo* involvement of aquaporin *NtAQP1* in mesophyll conductance to CO<sub>2</sub> has been provided by indirect measures (Flexas et al., 2006).

Although the name aquaporin appears to be justified in many cases, the idea that the primary function of some MIP proteins may not be restricted to water transport has found support and may involve solute transport or other regulatory functions (Hill et al., 2004). Indeed, the ability of some MIPs homologues to transport a wide range of small neutral molecules has also been inferred from structural studies showing that aquaporin have structural features that may explain their transport specificities. As mentioned above, aquaporin has a two-stage filter that defines, at least partly, its permeability. Thus, comparison of the narrow selectivity filter region (Ar/R region) of all 35 aquaporins of *Arabidopsis* showed that they exhibited a conserved overall Ar/R region but could be classified in eight subgroups based on their pore

configuration at the Ar/R region. Arg195 was found to be conserved in all members of aquaporins and positioned at the narrowest segment of channel. It was therefore suggested that although plant aquaporins show a common fold their distinct differences in the pore configuration likely results in divergent transport selectivities (Wallace and Roberts, 2004). For instance, all PIPs exhibited a uniform Ar/R signature characteristic of “true aquaporin”, i.e. high water transport aquaporins. In comparison, a much higher diversity in the pore configuration was observed for TIPs and NIPs which are organized into three and two structurally and functionally distinct subgroups with different transport selectivity and potentially distinct regulatory properties, respectively (Wallace and Roberts, 2004; Wallace et al., 2006). In the NIP group II (*NIP5;1*, *NIP6;1*, *NIP7;1*), the Ar/R selectivity filter close to the NPA pore region differs to that of NIP I and the predicted pore has an increased size than NIP I subgroups suggesting a permeability for larger solutes such as urea. This new property is, for unknown reason, linked to a reduced water permeability (Wallace et al., 2006). Finally, akin to their diverging sequences in the aquaporin family, SIPs exhibited a rather unusual pore configuration.

#### 1.2.4 Plant aquaporins expression and localization

A complete understanding of aquaporin functions requires a precise knowledge of their expression pattern in specific tissues, cell types and compartments. Specific tools such as DNA arrays carrying aquaporin gene specific probes or quantitative real-time RT-PCR have been used to monitor the respective abundance of aquaporins in various tissues, organs or stress conditions in *Arabidopsis thaliana* (Jang et al., 2004; Alexandersson et al., 2005; Boursiac et al., 2005), maize (Zhu et al., 2005; Hachez et al., 2006b) or rice (Sakurai et al., 2005).

Whole genome analysis using Affymetrix ATH1 array has also been initiated by the AtGenExpress consortium to study *Arabidopsis* transcriptome in various developmental stages and upon diverse stresses and hormone treatments (Schmid et al., 2005; Kilian et al., 2007). However, analyses of MIP transcripts in *Arabidopsis* by DNA arrays have been somewhat limited by the high homology of aquaporins. E.g. for some genes, probe sets present on the Affymetrix array are not specific and do not discriminate several isoforms (e.g. *PIP2;2* and *PIP2;3* or *PIP2;7* and *PIP2;8*). In addition, divergent results have emerged from such studies. In *Arabidopsis*, strong and low expression have been measured for *PIP2;7* and *PIP2;1*, respectively (Jang et al., 2004) whereas the opposite has been demonstrated in other studies (Alexandersson et al., 2005; Boursiac et al., 2005). However, such studies definitely

showed that in *Arabidopsis*, *PIP1* genes as well as *PIP2;1*, *PIP2;2*, *PIP2;7* are usually abundantly expressed in both roots and aerial parts. In addition, high responsiveness of plant aquaporins to a wide range of environmental cues has been reported. For instance, aquaporin transcripts have been shown to be differentially deregulated by water stress conditions such as osmotic, drought, salt, and cold stress or abscisic acid (ABA) treatments (Kreps et al., 2002; Seki et al., 2002a; Bray, 2004; Jang et al., 2004; Alexandersson et al., 2005; Boursiac et al., 2005; Zhu et al., 2005). In *Arabidopsis*, *PIP2;3* was upregulated in leaves upon salt stress and downregulated by drought stress in both roots and leaves. In contrast, *PIP2;5* was upregulated upon drought and cold stress (Jang et al., 2004; Alexandersson et al., 2005; Boursiac et al., 2005). Similarly, a transcriptome analysis of *Arabidopsis* root transporters revealed differential responses of aquaporins upon cation stresses. Thus, salt stress lead to an initial down-regulation of aquaporins followed by an up-regulation (e.g. *PIP2;1*, *PIP2;3* or *PIP2;7*), while  $\text{Ca}^{2+}$ -starvation triggered an general down-regulation of aquaporins such as *PIP2;1*, *PIP2;2*, *PIP2;3*, *PIP2;4* and TIPs.  $\text{K}^{+}$ -deprivation specifically affected only a small number of aquaporin isoforms such as *PIP1;3*, *PIP2;1* and *PIP2;2* (Maathuis et al., 2003).

Thus, although these studies gave valuable information regarding the presence of aquaporin transcripts in various organs or tissues, there is only very limited knowledge in *Arabidopsis* as well as in other plants regarding the cellular expression profile of individual aquaporins. Recently, cell-specific expression of aquaporin genes in *Arabidopsis thaliana* roots has been determined in a genome-wide analyses based on fluorescence-activated cell sorting and Affymetrix ATH1 microarray analyses (Birnbaum et al., 2003). Cell-specific expression of aquaporin genes has been recently well detailed in primary root tips of maize using in situ RT-PCR (Hachez et al., 2006b). All *ZmPIP* genes except *ZmPIP2;7* showed expression in primary roots with strong expression towards the elongation and mature zones. Immunodetection techniques have also been used in *Arabidopsis* to characterize aquaporin expression in various organs, cell types or compartments, although most antibodies cross-reacted with several members of subclasses of plant aquaporins (Robinson et al., 1996; Frangne et al., 2001; Kobae et al., 2006; Vander Willigen et al., 2006; Hachez et al., 2006b). In tobacco flower, differential expression has been found for PIP1 and PIP2 proteins during anther and stigma development (Bots et al., 2005a; Bots et al., 2005b).

The use of reporter gene systems has proven useful and gave most valuable informations regarding the expression of a few aquaporin genes so far. In *Arabidopsis thaliana*, the *in situ* localization of the  $\beta$ -glucuronidase reporter gene led to the elucidation of the expression of several aquaporin isoforms. Individual aquaporins had been shown to be highly expressed

during cell elongation and frequently in the region of vascular cells (Ludevid et al., 1992; Kaldenhoff et al., 1995; Javot et al., 2003). Thus, expression of *AtTIP1;1* and *AtPIP1;2* has been observed in expanding as well as differentiated cells in both roots and aerial parts (Ludevid et al., 1992; Kaldenhoff et al., 1995), whereas high expression of *AtNIP5;1* has been found in epidermal, cortical, and endodermal cells of root elongation zone but not in aboveground tissues (Takano et al., 2006). High expression of *PIP1;2* and *TIP2;1* has also been observed in vascular tissue and surrounding cells of roots and aboveground tissues in *Arabidopsis thaliana* (Kaldenhoff et al., 1995; Daniels et al., 1996). The presence of these aquaporin may raise water permeability and facilitate water transport from symplast to apoplast in the roots and assist the opposite phenomenon in the aerial parts of plants.

An *AtPIP2;2* promoter  $\beta$ -glucuronidase gene fusion indicated predominant expression in root cortex, endodermis and stele. These expression data together with decrease of root osmotic hydraulic conductivity of *pip2;2* knockout mutants provided the first evidence for the contribution of a single PIP aquaporin, *AtPIP2;2*, in root water uptake (Javot et al., 2003). Provided that AQPs function indeed as water channels *in vivo*, these localizations may mean that the corresponding MIP proteins could play a role in regulating bulk flow of water across membranes and/ or in maintaining turgor homeostasis during active solute exchange.

Another crucial issue is the membrane location of aquaporins. The high amino acid sequence identity between close aquaporin homologues (up to 97%) is a big challenge for the discrimination of single aquaporin isoform expression profiles at the protein level. On the other hand, the high abundance of many aquaporins has successfully allowed using biochemical methods for analyzing their expression. High resolution techniques such as mass spectrometry can distinguish between very close aquaporin homologues and, therefore, permit a precise inventory of aquaporins present in well-defined sub-cellular membrane fractions (Santoni et al., 2003; Alexandersson et al., 2004; Marmagne et al., 2004; Nelson et al., 2006). Historically, the assignment of plant MIPs to specific membrane locations has been biochemically proven for several isoforms and was further extended based on sequence homology. However, this is not necessarily true in all cases and recent evidence suggests that MIP proteins may have more than one location or may move depending on physiological states or environmental stresses (Barkla et al., 1999; Kirch et al., 2000; Ma et al., 2004; Vera-Estrella et al., 2004; Boursiac et al., 2005). Utilizing specific antibodies against several MIP members from *Mesembryanthemum crystallinum* (common ice plant), it has been suggested that their distribution might be more complex than previously thought. In fact, immunological

detection of the TIP member MIP-F confirmed that it is exclusively localized to a tonoplast fraction. However, signals for three other putative plasma membrane PIP members (MIP-A, -B, -C) were not clearly defined (Barkla et al., 1999). Proteins might cycle through endomembranes in a manner resembling the mammalian aquaporins to regulate water flux (Marples et al., 1998; Tamarappoo and Verkman, 1998). Microscopic analysis has revealed that plasma membrane localized PIP1 isoforms from *Arabidopsis* are also present in high abundance in plasma membrane invaginations, termed plasmalemmasomes. These might represent transitory structures connecting the plasma membrane and plant endosomes (Robinson et al., 1996).

In *Arabidopsis thaliana*, the use of GFP fusion protein has allowed to locate individual MIP proteins in plasma or vacuolar membrane as well as in intracellular vesicles (Reisen et al., 2003; Ma et al., 2004; Boursiac et al., 2005; Takano et al., 2006). By mean of GFP-fusion protein expressed in transgenic plants, a NIP protein involved in orthosilicic acid transport in rice has been localized on the plasma membrane of the distal side of endodermis and exodermis root cells (Ma et al., 2006). Similarly, TIP1;1-GFP and PIP1;1-GFP or PIP2;1-GFP fusion proteins, localized in the vacuolar and plasma membrane, respectively, were also observed to be relocalized into intracellular spherical structures after exposure to salt (Boursiac et al., 2005).

### 1.2.5 Regulation of plant aquaporins

Apart from transcriptional regulation (see 1.2.4) aquaporins are regulated by additional mechanisms acting through modifications at their protein structure (for a recent review see Chaumont et al., 2005).

#### 1.2.5.1 Phosphorylation

Several post-translational modifications have been found to regulate aquaporin activity. Phosphorylation of aquaporin seems to be an important mechanism for aquaporin regulation involved in a broad range of processes and that can itself be regulated by external parameters. Phosphorylation of soybean nodulin 26 at serine residue 262 is stimulated in response to water deficit, resulting in enhanced transport activity (Guenther et al., 2003). Furthermore, phosphorylation of a plasma membrane aquaporin in tulip has been shown to accompany opening of petals (Azad et al., 2004). This phosphorylation was temperature-dependent and reduced by low temperature. In contrast, chilling enhanced PIP2 phosphorylation in maize (Aroca et al., 2005). In *Arabidopsis thaliana*, regulation of the seed-specific *AtTIP3;1* by

phosphorylation has also been demonstrated (Maurel et al., 1995; Guenther et al., 2003). A conserved phosphorylation site exists in loop B of all plant PIPs (Johansson et al., 1998; Törnroth-Horsefield et al., 2006) and it has been established that the N- and C-terminal tails can be important domains for water channel regulation. In particular, compared with PIP1 proteins, PIP2 have a shorter N-terminal extension and a longer C-terminal end containing multiple putative phosphorylation sites (Schäffner, 1998; Chaumont et al., 2000; Johansson et al., 2000; Chaumont et al., 2001; Johanson et al., 2001). For instance, it has been shown that the water transport activity of the PIP2 member PM28A in spinach was regulated by phosphorylation at serine residue; upon hyperosmotic treatment a cytoplasmic serine residue was dephosphorylated (Johansson et al., 1998).

Interestingly, recent membrane proteomics studies revealed that the N-terminal tail of PIP2 members can be methylated at adjacent sites. Thus, Lys3 and Glu6 residues of *AtPIP2;1* can be dimethylated and monomethylated, respectively (Santoni et al., 2006). Measurements of water transport in plasma membrane vesicles indicated that this novel post-translational modification of aquaporins did not interfere with their intrinsic water permeability. However, it was suggested that methylation may represent a crucial step towards the identification of new regulatory mechanisms of plant membrane proteins (Santoni et al., 2006; Maurel, 2007).

#### 1.2.5.2 Regulation by pH and $\text{Ca}^{2+}$

The plasma membrane water permeability appears also to be influenced by divalent cations and pH (Gerbeau et al., 2002; Alleva et al., 2006). Addition of  $\text{Ca}^{2+}$  reduced cell hydraulic conductivity of *Arabidopsis* suspension cells and purified plasma membrane vesicles and  $\text{H}^+$  was shown to reversibly decrease water channel activity (Gerbeau et al., 2002). In addition, beneficial effect of inhibition of water transport by calcium during salt stress has been described (Cabanero et al., 2006; del Martinez-Ballesta et al., 2006). However, whether this inhibition results from direct inhibition of aquaporins or through a signaling cascades still remains to be elucidated. Because environmental stresses known to affect water transport trigger calcium signaling cascades,  $\text{Ca}^{2+}$  has also been linked to aquaporin regulation and aquaporin phosphorylation is largely mediated by calcium-dependent protein kinases (Johnson and Chrispeels, 1992; Johansson et al., 1996; Sjøvall-Larsen et al., 2006).

Interestingly, it has been shown that apoxia-inducing flooding of plants leads to inhibition of water uptake. It has been demonstrated that this down-regulation was accompanied by a sustained intra-cellular acidification (Tournaire-Roux et al., 2003). In experiments expressing *Arabidopsis* aquaporins (*AtPIP2;1*, *AtPIP2;2*, *AtPIP2;3* and *AtPIP1;2*) in *Xenopus* oocytes a

drop of intra-cellular pH resulted in a decrease of water conductance implicating a closure of aquaporins by protons. In *AtPIP2;2*, a histidine (His) residue at position 197 in Loop D was identified to be the major pH-sensing site under physiological conditions (Tournaire-Roux et al. 2003, Chaumont et al. 2005). In a structural model of *AtPIP2;2* with protonated His197, Loop D is folded over the pore and caused the closure of the protein (Tournaire-Roux et al., 2003; Chaumont et al., 2005).

### 1.2.5.3 Aquaporin interaction and trafficking

Multimerization can regulate the activity and function of membrane proteins (Veenhoff et al., 2002). The importance of aquaporin heteromerization was previously suggested *in planta* by analysis of PIP1 and PIP2 antisense *Arabidopsis* plants. Indeed, the inhibition of water transport in transgenic *Arabidopsis* with down-regulation of both PIP1 and PIP2 members was not more pronounced than in transgenic *Arabidopsis* with reduced expression of only PIP1s or PIP2s. The authors argued that PIP1 and PIP2 form a common water channel unit in the plasma membrane (Martre et al., 2002).

More recently it has been shown that the water transport ability of PIP isoforms can be enhanced by co-expression of PIP1 with PIP2 proteins (Fetter et al., 2004; Temmei et al., 2005). Thus, while *ZmPIP1;2* alone did not show water transport activity, co-expression of maize *ZmPIP1;2* and different PIP2 isoforms (*ZmPIP2;1/-2;4/-2;5* and even *AtPIP2;3*) in *Xenopus* oocytes resulted in an increase in water permeability compared with individual expression of these PIP isoforms (Fetter et al., 2004). In addition, the authors showed that co-expression of *ZmPIP1;2*-GFP fusion protein with *ZmPIP2* proteins enhanced the targeting of *ZmPIP1;2*-GFP to the plasma membrane or its stability. Since physical interaction was demonstrated by chromatographic co-purification using His-tagged *ZmPIP2* and *ZmPIP1;1*-GFP, it was suggested that the enhanced water permeability was the result of heteromerization of PIP1 and PIP2 isoforms, which improves targeting of PIP1 to the plasma membrane (Fetter et al., 2004; Chaumont et al., 2005). Heteromerization was also suggested for *Mimosa pudica* aquaporins *MpPIP1;1* and *MpPIP2;1* by co-immunoprecipitation of tagged proteins when co-expressed in COS7 cells (Temmei et al., 2005). Moreover, phosphorylation in loop B of *MpPIP1* was important for the positive effect on water transport after co-expression (Temmei et al., 2005). Although this phosphorylation was not required for physical interaction, an effect on water transport was only observed upon co-expression of *MpPIP1;1* with *MpPIP2*.

In contrast to these heterologous expression systems, PIP2-PIP1 interaction has now been clearly demonstrated in living maize cells using FRET and fluorescence lifetime imaging

microscopy (Zelazny et al., 2007). When expressed alone, several *ZmPIP1*s fused to the monomeric cyan fluorescent protein (mCFP) were retained in the endoplasmic reticulum, whereas *ZmPIP2*s fused to the monomeric yellow fluorescent protein (mYFP) were found in the plasma membrane (Zelazny et al., 2007). Interestingly, when co-expressed, mYFP::*ZmPIP2*s and mCFP::*ZmPIP1*s interacted resulting in relocalization of mCFP::*ZmPIP1*s to the plasma membrane. Additional evidence for the interaction of *ZmPIP1* and *ZmPIP2*s in maize roots was provided by co-immunoprecipitation of *ZmPIP1;2* with *ZmPIP2;1* using isoform-specific antibodies (Zelazny et al., 2007).

The importance of four amino acid substitution in loop E was demonstrated by their replacement in *ZmPIP1;1* with those from *ZmPIP1;2*. This replacement conferred to *ZmPIP1;1* similar properties like *ZmPIP1;2* upon co-expression in increasing oocytes membrane water permeability (Fetter et al., 2004). Thus, co-expression of *ZmPIP2;5* and *ZmPIP1;1* in *Xenopus* oocytes does not lead to an increase of the oocyte membrane water permeability unless the *ZmPIP1;1* loop E is replaced with that of *ZmPIP1;2*. It was concluded that *ZmPIP1;1* and *ZmPIP2;5* do not interact functionally in *Xenopus* oocytes and that loop E plays an important role in *ZmPIP1/PIP2* interactions (Fetter et al., 2004). However, FRET in living maize cells demonstrated that *ZmPIP2;5* interacts with *ZmPIP1;1*, enhancing its targeting to the plasma membrane. The authors suggested that *ZmPIP1;1* and *ZmPIP2;5* do physically interact, but this heteromerization does not increase the oocyte membrane water permeability because *ZmPIP1;1* would not be functional (Zelazny et al., 2007). Comparison of the structural models of *ZmPIP1;1* and *ZmPIP1;2* suggested that loop E might be important in propagating structural changes (i.e. multimerization) affecting the structure of the channel and, hence, its specificity (Chaumont et al., 2005).

These results suggest that PIP1-PIP2 heteromerization is required for *in planta* PIP1 trafficking to the plasma membrane and to modulate plasma membrane permeability. Accordingly, PIP1 aquaporins might need to be activated in the plant in order to function as water channels.

Additionally, molecular trafficking is an important regulation mechanism of aquaporins. Such regulation of aquaporin has been well described in humans. In kidney collecting duct epithelia, AQP2 containing vesicles were routed to the membrane in response to a hormonal stimulus (Brown, 2003). In plants, the regulation and redistribution of PIP and TIP aquaporins from *Mesembryanthemum crystallinum* has been shown to occur when plants were submitted to hyperosmotic stress or salt stress (Kirch et al., 2000; Vera-Estrella et al., 2004). Hyperosmotic stress induces a delocalization of a TIP protein from *Mesembryanthemum*

*crystallinum* (*McTIP1;2*) from the tonoplast to endosomal compartments. This delocalization could be blocked by inhibitors of vesicle trafficking processes and was linked to aquaporin glycosylation (Vera-Estrella et al., 2004). Similar redistribution was seen in *Arabidopsis* root upon exposure to salt stress (Boursiac et al., 2005). GFP fusions indicated a relocation of *AtTIP1;1* and *AtPIPs* into vacuolar substructures called bulbs after 45 min and 2 h, respectively. Eventually, plant death by RNAi inhibition of *AtTIP1;1* has been explained by a function of *AtTIP1;1* in sugar metabolism and vesicle trafficking (Ma et al., 2004).

Thus, trafficking appears to be an essential regulation mechanism for plant aquaporin activity and raises the question of their subcellular localizations. In fact, aquaporin localization may not be restricted to one compartment. For instance, only a preferential accumulation of *AtSIP* and *AtNIP2;1* in the endoplasmic reticulum has been reported. Studies have also reported presence of aquaporins in mitochondria in both animals (Amiry-Moghaddam et al., 2005; Calamita et al., 2005) and in *Arabidopsis thaliana* plants (Jones et al., 2006).

### 1.2.6 Integrated function of plant aquaporins inferred from transgenic plants

Aquaporins are presumed to participate in many different physiological processes (for recent review see Kaldenhoff and Fischer, 2006; Hachez et al., 2006a; Maurel, 2007), including photosynthesis (Uehlein et al., 2003), reproduction (Bots et al., 2005b) and restriction of root water uptake regulation by low pH values (Tournaire-Roux et al., 2003). Studies on the integrated function of aquaporins in plants have been somehow limited by the high genetic diversity of aquaporins in these organisms and other methodological difficulties such as the lack of specific inhibitors. Yet, there is now a substantial body of evidence in different plant species, based on alteration of aquaporin functions by various inhibitors (e.g. mercurials, silver or gold compounds). However, because of the overall toxicity of these inhibitors and their effects on other physiological processes, such studies are unspecific and make any analysis of aquaporin function at the tissue level difficult. In addition, some aquaporin isoforms have been shown to be mercury insensitive such as *PIP2;3* in *Arabidopsis thaliana* (Daniels et al., 1994). Nevertheless, several reports may suggest that aquaporins significantly contribute to water transport in plants (Tyerman et al., 1999; Niemietz and Tyerman, 2002). For instance, using mercury, a rapid drop in root elongation rate was shown in maize, suggesting a central role of aquaporins in this process (Hukin et al., 2002).

Modulation of aquaporin genes *in planta* offers more reliability and has become the strategy of choice to elucidate the function of aquaporins. Thus, most of our knowledge on the physiological relevance of aquaporins in plant water relations comes from analyses of

transgenic plants with modified expression of various aquaporins either from overexpression or from gene silencing by antisense or RNAi suppression (Kaldenhoff and Fischer, 2006; Hachez et al., 2006a).

The first evidence for a function of aquaporins in cellular water uptake and whole-plant water transport came from plants expressing antisense *PIP1* RNA reducing both *PIP1;1* and *PIP1;2* transcripts. Mesophyll protoplasts of these plants showed a reduced water permeability (Kaldenhoff et al., 1998). *Arabidopsis* plants expressing antisense *AtPIP1;2/1;1* or *AtPIP2;3* gene alone or together (double antisense) showed a reduction in transcript or protein levels for several PIP1 and/or PIP2 homologues (Kaldenhoff et al., 1998; Martre et al., 2002). The altered *PIP* expression resulted in a reduction of water permeability in isolated protoplasts as well as a decline in the total root hydraulic conductivity. Interestingly, plants developed a larger root system than the controls which was interpreted as a response to compensate for the reduced cell water permeability. Since the leaf hydraulic conductance was not changed with respect to the control, the overall hydraulic conductance of these plants was unaffected.

In tobacco, overexpression of *AtPIP1;2* significantly increased growth rate, transpiration rate, stomatal density and photosynthetic efficiency under favorable growth conditions, but caused faster wilting in drought conditions (Aharon et al., 2003). Reduced expression of several PIP1 homologues in tobacco *NtAQPI* antisense plants resulted in a significant decrease of protoplast membrane water permeability. However, in contrast to *Arabidopsis* PIP antisense lines, *NtAQPI* antisense tobacco did not show any increase in root mass (Siefritz et al., 2002). Instead, tobacco root hydraulic conductivity was reduced, plant water potential was decreased and plant transpiration was diminished. In addition, the diurnal epinastic leaf movement, a process involving high rates of cellular water transport was reduced, pointing to the importance of aquaporin-mediated water transport in this process (Moshelion et al., 2002; Siefritz et al., 2004).

Plants with impaired expression of a PIP1 aquaporin showed differences not only in water transport but also in CO<sub>2</sub>-dependent processes such as photosynthesis, or in stomatal and even mesophyll conductance (Siefritz et al., 2002; Uehlein et al., 2003; Flexas et al., 2006). The effect of mercuric compounds on CO<sub>2</sub> conductance in leaves also suggested an involvement of aquaporins in case of an increased gas transport rate (Terashima and Ono, 2002). Although, the physiological significance of CO<sub>2</sub> transport through AQP1 in mammals is a matter of debate, CO<sub>2</sub> permeability in plants as demonstrated for several aquaporins may imply a function in photosynthesis, one of the most important metabolic processes in plants.

Studies on RNAi transgenic *Arabidopsis* plants with reduced *AtTIP1;1* showed a lethal phenotype. Gene expression profiling and metabolite analysis suggested a function in sugar metabolism and vesicle-based metabolite routing through or between pre-vacuolar compartments and the central vacuole (Ma et al., 2004).

Although these transgenic approaches resulted in valuable information about the potential involvement of aquaporins in different processes, they could not resolve the contribution of single aquaporin members. In fact, suppression by antisense or RNAi typically leads to silencing of several isoforms which makes interpretation difficult; a differential suppression of different isoforms could be an explanation for some controversial results. Similarly, interpretations based on overexpression studies have to be taken with care. A recent work demonstrated that *Arabidopsis* and tobacco plants overexpressing PIP1;4 or PIP2;5 exhibited retarded seed germination and seedling growth under drought, whereas germination was facilitated under cold stress (Jang et al., 2007a). In this study, the authors nicely showed that the overexpression of an aquaporin (PIP1;4 or PIP2;5) also affects the expression of endogenous *PIP2* genes and thereby impacts on plant development under various stress conditions. Similar results were provided with other aquaporins and other plants (Jang et al., 2007b). Thus, overexpression does not reflect the function of the modulated protein as there is a strong influence on several endogenous transcripts; consequently, physiological functions of individual aquaporins cannot be deduced from those studies due to unknown effects on the aquaporin complement.

The use of knockout mutant might provide a more specific approach to address the function of a given isoform *in planta*. However, studies using knockout mutants are very limited. To date, in *Arabidopsis*, *pip2;2* T-DNA knockout lines demonstrated the involvement of this aquaporin in root water uptake (Javot et al., 2003). Although *Atpip2;2* knockout mutants did not reveal any visible phenotype, a reduced osmotic hydraulic conductivity of roots has been measured in two *pip2;2* mutants compared with the wild-type by cell pressure probe and root exudation measurements. These data provided evidence for the contribution of *AtPIP2;2* in root water uptake. In addition, the authors indicated that the disruption of *PIP2;2* was not compensated for by enhanced expression of any other *PIP* homolog. Accordingly, the authors claimed the observed phenotype indicated that *AtPIP2;2* and *AtPIP2;3*, its closest homologue (showing 97% amino acid identity), have evolved with non-redundant functions. Thus, analysis on aquaporin knockout mutants will surely contribute to a better understanding of the integrated functions of individual aquaporin isoform in plants.

### 1.3 Goals of the project

To further our molecular understanding of plant water relations the major aim of this work was to provide new insights into individual aquaporin isoforms and the processes and functional contexts in which they are involved. I focused on the *Arabidopsis* PIP2 subfamily with eight members; all have been shown to facilitate the permeation of water or at least to possess the critical amino acids indicating water permeation (see above). Furthermore, PIP2 members exhibit a high amino acid sequence homology. Thus, a central issue of this work was asking whether they might exhibit differential or mostly redundant, overlapping functions.

Several molecular genetic, biochemical and physiological approaches were undertaken to infer their roles in plant physiology:

- Transgenic *PIP2*-promoter-reporter (GUS) lines were examined to comprehensively elucidate the organ and cellular expression patterns of all members.
- A collection of *pip2* knockout mutants was established as an important tool to study and compare the effects of individual loss-of-function, since overexpression and antisense-suppression had turned out to be less specific. To analyze the importance of single *PIP2* genes, the phenotypes of the knockouts were analyzed under different conditions including water stress. Furthermore, the transcriptome levels and PIP protein levels were analyzed for differential alterations provoked by the mutation.
- Public expression data were mined to identify co-expressed genes and stress-responsive transcriptional patterns of *PIP2* genes.
- So far only a few examples could demonstrate that a single aquaporin was involved in plant water relations. Therefore, a method using deuterated water as a tracer and subsequent mass spectrometric analysis was adapted to study non-invasively the impact of PIP2 on water uptake using *pip2* knockout mutants.

Based on these analyses, a differential and mostly non-redundant function for the closely related *PIP2* genes in *Arabidopsis* is proposed and their individual involvement in plant water relation discussed.

## 2 MATERIALS AND METHODS

### 2.1 Materials

#### 2.1.1 Plant materials

Insertion lines and wild-type plants used in this study were of *Arabidopsis thaliana* ecotype Col-0 except mutant line FLAG572D12 that was of ecotype Ws (Wassilewskija). Informations about *AtPIP2* insertional mutant candidates were obtained by screening the publicly accessible SIGnal T-DNA Express database of the SALK Institute (<http://signal.salk.edu/cgi-bin/tdnaexpress> (Alonso et al., 2003). Mutant candidates from various sources were retrieved; i.e. from the SALK, the GABI-Kat (Rosso et al., 2003), the JIC SM (Tissier et al., 1999), the Genoplante FLAGdb/FST (Balzergue et al., 2001) and the SAIL collections (Sessions et al., 2002). The seeds were purchased from the Nottingham *Arabidopsis* Stock Center (NASC) or from the *Arabidopsis* Biological Resource Center (ABRC, Ohio state University, USA, <http://www.biosci.ohio-state.edu/pcmb/Facilities/abrc/abrchome.htm>). GABI lines and FLAG lines were purchased from GABI-Kat (MPI, Köln, Germany) and the Institut National de la Recherche Agronomique (INRA, Versailles, France), respectively. Insertional mutants used and isolated in this work are listed in Table 1.

Plant transformation with *PIP2* promoter::GUS constructs or *PIP2* promoter::PIP2-ORF-GFP constructs were performed on *Arabidopsis thaliana* Col-0 and C24 or Col-0, respectively. Transgenic plants expressing *PIP2* promoter::GUS fusion protein for *PIP2;1*, *PIP2;2*, *PIP2;3* and *PIP2;4* were established earlier in the lab in C24 background (Franck, 1999). In addition, seeds of transgenic plants expressing a *PIP2;5* promoter::GUS fusion protein were obtained from a colleague (Dr. Ulrich Hammes, Molekulare Pflanzenphysiologie, FAU Erlangen) within the priority program “Dynamics and Regulation of Plant Membrane Transport” (DFG-Schwerpunktprogramm 1108 "Dynamik und Regulation des pflanzlichen Membrantransportes").

**Table 1. *AtPIP2* insertional mutants.**

Single and double mutants used in this work are listed. Absence (A) or presence (P) of transcripts expression was tested by RT-PCR. Mutants showing loss-of-transcripts are labeled in bold. Nd: Not determined. collections used: AMAZE (ZIGIA project, MPI, Köln, Germany), JIC SM (Tissier et al., 1999), GABI (Rosso et al., 2003), SAIL (Sessions et al., 2002), SALK (Alonso et al., 2003) and FLAG (Balzergue et al., 2001).

### 2.1.2 Vectors and bacteria

The plasmid vectors and *E. coli* bacteria used in this work are listed below. For plant transformation the *Agrobacterium tumefaciens* strain GV3101 (pMP90) was used.

Bacteria:*E. coli* DH-5 $\alpha$ *E. coli* DH-5 $\alpha$  (DB3.1) (Gateway, Invitrogen, Karlsruhe, Germany)*E. coli* BL-21 (DE3)Vectors:

pDEST15 (Gateway, Invitrogen, Germany)

pDONR221 (Gateway, Invitrogen, Germany)

pGEM-T easy vector system (Promega, Germany)

pBGWFS7 (containing T-DNA; Gateway, Invitrogen, Germany) (Karimi et al., 2002)

pK7FWG2 (containing T-DNA; Gateway, Invitrogen, Germany) (Karimi et al., 2002)

**2.1.3 Antibiotics****Table 2. Antibiotic stock and working solutions. Stock solutions were stored at -20°C.**

<b>Antibiotics</b>	<b>Stock solution (mg/ mL)</b>	<b>Working concentration (<math>\mu</math>g/ mL)</b>
Ampicillin (Roche, Mannheim, Germany)	100 (in water)	100
Gentamicin (Roche, Mannheim, Germany)	50 (in water)	25
Kanamycin (Sigma, Deisenhofen, Germany)	50 (in water)	50
Rifampicin (Sigma, Deisenhofen, Germany)	50 (in methanol)	100
Spectinomycin (Sigma, Deisenhofen, Germany)	100 (in water)	100

**2.1.4 Restriction enzymes and Modifying enzymes**

The restriction enzymes and their buffers were obtained from MBI Fermentas Life Sciences (St. Leon-Rot, Germany) or New England Biolabs (Frankfurt, Germany). All the modifying enzymes like T4-DNA-ligase, DNase, RNase A and H, T4-DNA-Polymerase, Reverse transcriptase Superscript II, Rnase H, *Taq* DNA Polymerase, *Pfu Turbo*<sup>®</sup>, alkaline phosphatase, etc. were purchased from Q-Biogene, MBI Fermentas, Stratagene, Roche, Sigma, Gibco-BRL, Amersham Pharmacia, and Promega.

Gateway cloning enzymes were purchased from Invitrogen (Karlsruhe).

**2.1.5 Antibodies**Antiserum:

- Rabbit brown antiserum against C-terminus RASGSKSLGSAANV of *AtPIP2;2* (=2;1, 2;3) fused to keyhole limpet hemocyanin (Heidi Sieber & Anton Schäffner).

- Rabbit 5.1 antiserum against N-terminus  
MEGKEEDVRVGANKFPERQPIGTSAQSDKDYKEPPPAPFFEP of *AtPIP1;1*  
expressed as a GST-fusion protein (Heidi Sieber & Anton Schäffner)

#### Secondary antibody:

Anti Rabbit IgG, Cy<sup>TM</sup>5-Linked (from goat; Amersham Pharmacia, Freiburg)

#### **2.1.6 Isotopically labeled compounds**

[ $\alpha$ -<sup>33</sup>P]dATP (>2500 Ci/mmol), Redivue stabilized and regular form (Amersham Pharmacia, Freiburg)

[ $\gamma$ -<sup>33</sup>P]ATP (>2500 Ci/mmol), Redivue (Amersham Pharmacia, Freiburg)

D<sub>2</sub>O (90%) (Merck)

#### **2.1.7 Oligonucleotides and sequencing**

Primers were designed using Primer3 software ([http://frodo.wi.mit.edu/cgi-bin/primer3/primer3\\_www.cgi](http://frodo.wi.mit.edu/cgi-bin/primer3/primer3_www.cgi)) and oligonucleotides were obtained either from the Helmholtz Zentrum München facility or from Thermo Electron (Ulm, Germany). Stock solutions were prepared at a concentration of 200  $\mu$ M. All primers used in this work are listed in Annex 1.

#### **2.1.8 Chemicals**

All commonly used media chemicals used in this study were of molecular biology grade and purchased from commercial sources: Amersham Pharmacia (Freiburg), Bio-Rad Lab GmbH (München), Gibco-BRL (Eggenstein), Merck (Darmstadt), Roche (Mannheim), Roth (Karlsruhe), Serva (Heidelberg) and Sigma (Deisenhofen).

Detergent Silwet L-77 was purchased from Lehle Seeds (Round Rock, Texas, USA).

Plasmid isolation, agarose gel extraction, PCR purification kits and other purification columns used in this work were obtained from Qiagen (Hilden) or Amersham Pharmacia (Freiburg). Special chemicals are detailed in the corresponding methods below.

#### **2.1.9 Medium and solutions**

Common media, buffers and solutions were prepared according to recipe and informations obtained from the laboratory manual Current Protocols in Molecular Biology (Ausubel et al., 1987 with quarterly updates). Special media and solutions are depicted in the corresponding methods below.

## 2.1.10 Apparatus

**Table 3. Apparatus and equipment**

Name	Company
ABI PRISM 7900HT	Applied Biosystem, Foster City, USA
Bio-Rad Gel Doc 2000	Bio-Rad Lab GmbH, Munich, Germany
Centrifuge rotanta 460R	Hettich, Tuttlingen, Germany
Electroporation Gene Pulser™	Bio-Rad Lab GmbH, Munich, Germany
Eppendorf centrifuge 5451C	Eppendorf, Hamburg, Germany
FLA-3000 image reader	Fuji, Düsseldorf, Germany
Illuminated refrigerated incubator shaker Innova 4340	New Brunswick scientific, Nürtingen, Germany
Light microscope Olympus SZ-40	Olympus optical, Hamburg, Germany
MicroGrid II robot	BioRobotics, Cambridgeshire, England
Microtiterplate centrifuge 4K15C	Sigma GmbH, Osterode, Germany
MultiCycler PTC-200	Biozym, Oldenburg, Germany
Nanodrop ND-1000 spectrophotometer	Kisker-biotech, Steinfurt, Germany
Precision Balance	Sartorius, Göttingen, Germany
Rotary Kilns for Hybridization	Bachofer GmbH, Munich, Germany
Scintillation counter LS 6000SC	Beckman Coulter, Krefeld, Germany
SORVALL RC 5B+ superspeed centrifuge	DuPont Instruments GmbH, Bad Homburg, Germany
Spectrophotometer DU640	Beckman Coulter, Unterschleissheim, Germany
Speed-Vac UNIVAPO 100H	UNIEQUIP, Martinsried, Germany
Stereomicroscope Leica MZ16F with Leica DFC 320 camera	Leica, Munich, Germany
Table centrifuge Mikro 24-48R	Hettich, Tuttlingen, Germany
Thermocycler UNO-Thermoblock	Biometra, Göttingen, Germany
Ultracentrifuge LE-70	Beckman Coulter, Munich, Germany
UV Stratalinker	Stratagene, La Jolla, USA
VacuGene-XL Blotting	Amersham Pharmacia, Freiburg, Germany
Zeiss Axioskop (fluorescence microscope)	Zeiss, Jena, Germany

## 2.2 Methods

### 2.2.1 Culture of *Arabidopsis thaliana* plants

#### 2.2.1.1 Growth conditions

*Arabidopsis thaliana* plants were grown on soil or in vitro in a growth chamber under the following environmental parameters (or otherwise mentioned): 16-h/8-h light/dark cycle, 150-200  $\mu\text{mol}\cdot\text{m}^{-2}\cdot\text{s}^{-1}$  light intensity, 24/20°C day/night temperature and relative humidity ranged from 45 to 60%. In all cases, seeds were vernalized in the dark at 4°C for 2 to 5 days to synchronize germination and further placed in growth chamber.

#### 2.2.1.2 Growth in soil, crossing, seeds harvesting and storage

For growth in soil, seeds were placed onto trays filled with a 3:1 soil: sand mixture, vernalized and then placed in growth chamber. Plant material was collected 5 h after the onset

of light and used either immediately for analyses or frozen in liquid nitrogen and stored until further use at  $-80^{\circ}\text{C}$ .

Double *pip2* mutant were obtained by crossing *pip2* single mutant plants together. *Arabidopsis* plants were grown until mature flowers are present and at a stage where they are not open, yet not closed (4 to 6 weeks). An inflorescence is chosen and all the flowers that are too young or too old as well as all other plant parts in the immediate vicinity (flowers, siliques) were removed leaving 2-3 flowers and a free work environment. Using very fine forceps (Dumont No. 5) sepals, petals and stamen of a recipient flower are removed leaving only the pistil. During all the procedure, care has to be taken not to damage recipient pistil and its stigma. Pollen is then obtained from a donor plant by getting fully mature flowers and removing the stamens. These stamens, containing pollen grains, are used to place pollen on the top of the prepared ovaries. This step is repeated at least twice to ensure proper pollination. Each pollinated inflorescence is labeled accordingly and ovaries were let developing and seeds harvested once siliques were dry. Siliques should develop in about 5 days. If several crosses are done in a row, forceps were cleaned by dipping them in 95% ethanol (v/v) followed by rinsing with distilled water.

For mass harvesting of seeds, it was stopped watering the plants after the first siliques are beginning to turn brown (about two months). The plants were allowed to dry out and seeds from yellow brown siliques were harvested by gently tapping the dried plants onto a sheet of paper. Seeds were then transferred in seed packets and allowed to dry for one more week in a dessicator before being stored at room temperature.

### **2.2.1.3 Seed sterilization**

For in vitro cultures, seeds in an Eppendorf tube were surface-sterilized under a sterile bench with 70% (v/v) ethanol for 1 min followed by soaking in 30% (v/v) commercial bleach solution Klorix (DanKlorix, Colgate-Palmolive GmbH, Germany) for 5 min and then rinsed four times in sterile double-distilled water.

### **2.2.1.4 *In vitro* culture on solid medium**

Standard medium (SM) for in vitro culture was composed of 0.5X Murashige and Skoog Basal medium (Sigma, Germany) supplemented with 1.5% (w/v) sucrose and 0.5% (w/v) Gelrite (Duchefa, The Netherlands), pH 5.7 adjusted with KOH. Medium was autoclaved (20 min,  $120^{\circ}\text{C}$ ) and square Petri dishes (120 mm x 120 mm x 17 mm, Greiner bio-one, Germany) were poured with 75 mL SM medium each. Surface-sterilized seeds were sown

onto solidified medium and plates were wrapped with parafilm and placed at 4°C for stratification before being transferred into growth chamber in a vertical orientation.

#### **2.2.1.5 Hydroponic culture**

Nutrient solution for hydroponically grown plants was prepared according to Gibeaut et al. (1997; Table 4). Seed holders (1.5 mL Eppendorf tubes) were overfilled with a sterile growth gel. The gel contained 0.65% (w/v) agar (Plant Cell Culture tested, Sigma, Germany) and 0.5X hydroponic nutrient solution dissolved in double distilled water and was autoclaved prior to pouring of the Eppendorf tubes. Once the gel has solidified, 1-2 seeds were placed on the top of the gel in every tube which were then wrapped with saran wrap and vernalized in the dark at 4°C for 2 days to synchronize germination. The tubes were then transferred to a home-made hydroponic rack containing 56 holes and placed over a 15 liters hydroponic container filled with deionized water and placed in the growth chamber. Hydroponic racks and containers were opaque to produce healthy roots and to prevent growth of algae. To maintain high humidity and sterile conditions, the hydroponic containers were covered with a transparent plastic box. Standard growth conditions of the growth chamber were used (Method 2.2.1.1). After about six days, the Eppendorf tubes were cut at the bottom to allow roots to grow through the agar and reach the medium and placed in a new hydroponic box filled with 15 liters of fresh hydroponic medium. After cutting, the bottom of the tubes should be submerged in the nutrient solution. Care was taken to avoid cutting of the root tip of the seedlings. At this stage, the plastic cover was gradually elevated to prevent stress of the young seedlings. At day 10 to 12, the cover can be completely removed and growth conditions were changed to 11.5 h/12.5 h light/ dark cycle. The plants were then allowed to grow for 10 more days (ultimately, three-week-old plants).

**Table 4. Hydroponic medium composition (Gibeaut et al., 1997)**

To control the pH MES was additionally added.

<b>Macro-elements</b> (200X stock solutions, autoclaved)	250 mM KNO <sub>3</sub>
	300 mM Ca(NO <sub>3</sub> ) <sub>2</sub>
	150 mM MgSO <sub>4</sub>
	100 mM KH <sub>2</sub> PO <sub>4</sub>
<b>Micro-elements</b> (1000X stock solutions, autoclaved)	50 mM KCl
	50 mM H <sub>3</sub> BO <sub>3</sub>
	10 mM MnSO <sub>4</sub>
	2 mM ZnSO <sub>4</sub>
	1.5 mM CuSO <sub>4</sub>
	0.075 mM (NH <sub>4</sub> ) <sub>6</sub> Mo <sub>7</sub> O <sub>24</sub>
	100 mM Na <sub>2</sub> SiO <sub>3</sub>
72 mM Fe-EDTA	
MES is then added (0.5 g/L, w/v) and pH adjusted to 5.7 with KOH	

### 2.2.1.6 Growth measurements on *in vitro* culture

For growth measurements, surface sterilized and vernalized seeds were allowed to germinate on SM medium (Method 2.2.1.4) and 4-days-old wild-type and mutant seedlings grown on a vertical position were then transferred and placed with roots pointing downward onto new vertical Gelrite plates supplemented (or not) with various solutes; 50 or 100 mM NaCl, KCl or 200 mM Sorbitol. Each plate contained 5 to 6 mutant and wild-type seedlings (3 genotypes, i.e. wild-type and 2 mutants were placed per plate). All experiments were repeated 3 to 5 times. For the kinetics, increases in root length were measured with a ruler every day for 7 days. Means  $\pm$  standard deviation (SD) of the root length were calculated for each experiment (n = 5 to 6).

Relative root growth was calculated as the percentage of final root length of the mutants over the final root length of the wild-type plants in the same plate. Mean  $\pm$  standard error (SE) of all experiments (n = 5 to 6 plants per experiment independently repeated 3 to 5 times) were calculated and p-value were determined using an unpaired t-test assuming unequal variance and with 95% confidence (p < 0.05).

### 2.2.1.7 Leaf water loss measurement using detached-rosette assay

For leaf water loss measurements, plants were grown on soil with standard growth conditions for 1 week and then under short day conditions (11.5 h/12.5 h light/ dark cycle). Plants were grown under these conditions for 2 more weeks. The decline of fresh weight of excised rosette leaves from 21 day old plants was determined to compare the speed of loss of water by the leaves from wild-type and *pip2* mutant plants. The whole rosette was detached from the plant, weighed and left at room temperature (25°C, 55% humidity) in a laminar flow bench with

continuous ventilation. Water loss was measured by weighing the plants every one hour for 4 hours. Four separate plants were used for each genotype and experiment was repeated 3 times ( $n = 3$ ). Decline in fresh weight was expressed in percentage of the initial fresh weight and mean  $\pm$  SE of the 3 independent experiments were calculated and used for comparison of the different genotypes. P-values were calculated using an unpaired t-test assuming unequal variance and a 95% confidence was chosen ( $p < 0.05$ ).

#### **2.2.1.8 Root bending assay (gravitropism response)**

Wild-type and *pip2 Arabidopsis* mutant seeds were germinated on SM medium (Method 2.2.1.4) for 4 days under standard conditions and in a vertical position. Each plate contained 5 to 6 mutant and wild-type seedlings (3 genotypes, i.e. wild-type and 2 mutants were placed per plate). The plates were then turned 90° and the seedlings grew in their new horizontal orientation for 24 h. Plants were photographed every one hour for 8 h and a final photograph was taken at 24 h using a digital camera. Roots that reoriented completely to the new gravity vector resulting in vertical growth were considered to have a bending angle of 90°.

#### **2.2.1.9 Analysis of deuterium (D) translocation in plant**

##### Plant material and growth conditions

*Arabidopsis* wild-type and *pip2* mutant plants were grown hydroponically in a growth chamber (Methods 2.2.1.1 and 2.2.1.5). In order to have controlled and reproducible conditions, 19 days-old plants were transferred into a sun simulator (Helmholtz Zentrum München-Institute for Soil Ecology-Department of Environmental Engineering, Neuherberg, Germany). In the sun simulator, the following conditions were set: 16-h/8-h light/dark cycle, 450 to 500  $\mu\text{mol m}^{-2} \text{s}^{-1}$  light intensity, 22°C and 50% relative humidity. Due to the changing conditions plants are stressed when put in the sun simulator. Consequently, before starting the experiment, plants are left in the sun simulator 3 days for accommodation. Fresh hydroponic medium containing 1 mL of a 90% D<sub>2</sub>O solution per 15 L hydroponic medium with  $\delta\text{D} = -75\%$  was prepared. A big bottle was used to have enough isotopically identical medium that was further distributed in new hydroponic containers. After placing the new hydroponic containers in the sun simulator, it was left for about 2 h to restore the conditions (i.e. temperature, humidity).

##### Leaf and water sampling

Hydroponic racks with the plants were transferred in the new containers with deuterated water. Experiment started 5 to 6 hours after the onset of the light. Prior sampling, each plants

was given a name (e.g. A1, A2, A3, etc) in order to harvest and weigh roots of each plants at the end of the experiment. Plants and water were then collected at the corresponding time point to have a 24 hours kinetic study (0, 20 min, 40 min, 60 min, 80 min, 100 min, 2 h, 3 h, 4 h, 5 h, 6 h, 8 h and 24 h). Three plants and water samples (1 mL water per sample) were collected per time point. For plants, the entire rosette was harvested, placed into gas-tight glass vials tightly closed to prevent evaporation and stored at -20°C until the water could be extracted for isotopic analysis. Water samples from the medium without deuterium were also collected as a reference.

Atmospheric water vapor was also collected to measure its deuterium content. Air was continuously drawn from the sun simulator and pumped through a moisture freezing trap immersed in a dry ice-acetone mixture.

#### Sample preparation and analysis

Water from rosette leaves was extracted by cryogenic vacuum distillation. Rosette leaves were frozen in liquid nitrogen for about 10 min and fixed on a cryogenic distillation device. The system was then evacuated and isolated from the vacuum pump. The rosette leaves were boiled with a heating device and whole leaf water was collected in a tube immersed in liquid nitrogen. To obtain unfractionated water sample, extraction must proceed to completion and was therefore carried out for 2 h. The collection tubes were then stored in the freezer until processed for isotopic analysis. For each sample, rosette dry and fresh weight, water volume (fresh weight – dry weight) and relative water content ((fresh weight – dry weight) / fresh weight × 100) were measured.

The hydrogen isotope ratios (D/H) of water samples were measured twice by standard mass spectrometry (Delta-S, Finnigan MAT, Germany) and were expressed in parts per thousand

$$(\text{‰}) \text{ as: } \delta D = \left( \frac{R_{\text{sample}}}{R_{\text{standard}}} - 1 \right) \times 1000 \text{ (where R is the respective D/H ratio)}$$

relative to the Vienna-Standard Mean Ocean Water (V-SMOW) (absolute ratio is D/H = 0.00015576).

The  $\delta D$  measurements of water samples have a precision of  $\pm 1\text{‰}$ .

#### Fitting of the model

For each time point, mean values of measured leaf isotopic content were calculated. Fitting routines were then performed in Excel using equation 12 (see below Results 3.3.4). For each

time point difference between measured and modeled values were calculated. The sum of the squares of these differences was then determined and values for  $q$  and  $f$  were adjusted to get the lowest sum of the squares as possible. All other parameters (e.g. humidity) were constant and initially entered in the model.

## 2.2.2 Microbiological methods

### 2.2.2.1 Preparation of competent cells

A single colony of bacteria was inoculated into 2.5 mL of Rich Broth medium (RB) in a plating tube and cultivated overnight at 37°C with moderate shaking (250 rpm). An aliquot of 2.5 mL of culture was then subcultured in 250 mL RB medium containing 20 mM MgSO<sub>4</sub> and grown to an OD<sub>590</sub> of 0.4 to 0.6.

The suspension was centrifuged at 5000 rpm for 5 min at 4°C. The supernatant was discarded and the bacteria pellet resuspended carefully in 100 mL of ice-cold TFB1 and kept on ice for 5 min. The bacteria suspension was centrifuged at same speed. The new pellet was resuspended gently in 10 mL cold TFB2 and incubated on ice for 15-60 min. One hundred microliters were aliquoted in ice-cold Eppendorf tubes, immediately frozen in liquid nitrogen and stored at -80°C.

To assure the efficiency of transformation the prepared competent cells were tested. Plasmid DNA containing 100, 10, 1 and 0.1 pg were added to 100 µL competent *E. coli* competent cells and placed on ice for 30 min. Cells were then incubated in a 42°C water-bath for 30 sec and immediately placed on ice for 2-3 min. After addition of 900 µL SOC medium, samples were incubated at 37°C in a water-bath for 1 hour. Cells were mixed from time to time. After incubation, cells were centrifuged at 4000 g for 5 min. The supernatant was discarded, the pellet re-suspended in about 100 µL SOC medium and plated onto LB medium agar plate containing appropriate antibiotics. The plates were incubated overnight at 37°C.

#### TFB1

30 mM KOAc (potassium acetate)

100 mM RbCl

10 mM CaCl<sub>2</sub>

50 mM MnCl<sub>2</sub>

15% glycerol

pH adjusted to 5.8 with acetic acid

## TFB2

10 mM MOPS  
75 mM CaCl<sub>2</sub>  
10 mM RbCl  
15% glycerol  
pH adjusted to 5.8 with acetic acid

Both solutions were filtered sterilized using 0.45 µm filter (Millipore, Germany).

### **2.2.2.2 Transformation of competent cells**

A 100 µL aliquot of deep frozen competent cells is thaw on ice for 10 min and mixed with 5-10 µL of template DNA (ligation assay, Plasmid DNA). After incubation for 30 min on ice the mix is exposed to 42°C for 1 min and transferred on ice for 2 to 3 min. In order to allow expression of the antibiotics resistance, 900 µL of LB medium are added and bacteria are incubated for 1h in a 37°C water bath. Bacteria are then plated onto agar plate and incubated overnight at 37°C. The same transformation procedure was used independently of the plasmid (pDONR221, pK7FWG2, pBGWFS7). In case of Gateway-based vectors containing the ccdB gene, *E. coli* DB3.1 strain was used.

### **2.2.2.3 Transformation of *Agrobacterium tumefaciens***

Plasmids DNA were transferred into *Agrobacterium tumefaciens* by electroporation. A 100 µL aliquot of competent *Agrobacterium tumefaciens* strain GV3101 containing an appropriate helper Ti plasmid (pMP90) was thaw on ice. One µL of plasmid DNA (roughly up to a few 100 ng) is added to the cells and mixed on ice. The mixture is then transferred to a pre-chilled 0.2 cm electroporation cuvette. The electroporation was carried out as recommended for *E. coli* by the electroporator's manufacturer with slight modifications:

Capacitance: 25 µF

Voltage: 2.48 kV

Resistance: 400 Ω

After a pulse, the time constant should be at least larger than 9.1 (optimal is 9.4 to 9.6) to give a relevant number of transformants. A control without plasmid DNA was always done in parallel. Immediately after electroporation, 1 mL of SOC medium is added to the cuvette,

gently resuspended and transferred to a 15 mL culture tube with SOC medium. Cells were then incubated at room temperature for 60-90 min with gentle agitation. The cells were collected by gently centrifuging at 5000 rpm for 2-3 min. A part of supernatant was discarded and the cells resuspended by gently pipetting in the remaining supernatant. Cells (1/2 and 1/4 of total) were spread onto LB agar plate with appropriate antibiotic selection (Rifampicin and Gentamicin for agrobacteria and appropriate antibiotic for T-DNA vector) and incubated at 28-30°C for 2 to 3 days.

#### **2.2.2.4 *Agrobacterium tumefaciens*-mediated plant transformation**

Transformed *Agrobacterium tumefaciens* strain GV3101 carrying the construct of interest within its T-DNA were used to transform *Arabidopsis thaliana* plants by the floral dip procedure (Clough and Bent, 1998). *Arabidopsis* plants were grown over long day (16h, 22°C) in pots to flowering stage. Once the primary bolt was formed, it was clipped in order to get multiple secondary bolts per plants. Siliques already formed were also clipped to achieve higher transformation rates by eliminating non-transformed seeds. Agrobacteria were grown overnight at 28°C to stationary phase in sterilized LB medium (1:100 bacteria in 200 mL LB medium). The culture was then centrifuged for 20 min at room temperature at 5500 g and then resuspended in a 5% (w/v) sucrose solution to a final OD<sub>600</sub> of approximately 0.8. Before dipping, Silwet L-77 was added to the suspension to a final concentration of 0.05% (v/v). The solution was transferred to a beaker, and plant inflorescences were dipped for about 5 seconds into this solution. The same solution (100-200 mL) can be used for 2 to 3 small pots. Care was taken that only above-ground tissues were submerged and not leaves and soil. Dipped plants were then covered with a transparent plastic bag to maintain humidity and kept in a low light location for one day. Plant were then returned to the growth chamber and grown until siliques were brown and dry.

The first generation of seeds (T1) was collected, surface sterilized and grown either on soil and selected on the basis of BASTA resistance or in vitro in MS-agar solid medium (0.5X Murashige and Skoog Basal medium/ 1.5% sucrose/0.8% Agar, pH 5.8 with KOH) supplemented with appropriate selection antibiotics. Transformation rates are theoretically around 1%. After about 15-days of growth, transgenic seeds were able to germinate and produce green leaves in the presence of antibiotics while the non-transgenic seeds were not able to grow with true green leaves. The positive seedlings (transgenic lines) were transferred into soil trays and allowed to grow for the next generation of seeds (T2). At least, three independent transformant lines for each construction were used for further analyses.

### 2.2.3 Nucleic acid isolation

#### 2.2.3.1 CTAB DNA Minipreparation from plant tissue

A small leaf (or part of inflorescence) was squeezed with small pestle (e.g. flamed blue tip) in an Eppendorf tube and 250  $\mu$ L extraction buffer were then added. The tube was vortexed briefly and placed in a 65°C water bath for at least 10 min and 200  $\mu$ L of chloroform-isoamylalcohol (24:1) were added, tube vortexed vigorously and thoroughly and subsequently centrifuged at full speed for 2 min in a table-top centrifuge. The upper aqueous phase was transferred (care was taken not to touch the interface) into a new Eppendorf tube containing 1  $\mu$ L of 1% LPA. For DNA precipitation, 3 volume of absolute Ethanol p.a were added, mixed and left at -20°C for 20 min or longer. This step was followed by a 15 min centrifugation at 4°C and full speed in a table-top centrifuge. DNA pellet was then washed once with 70% Ethanol p.a., centrifuged at full speed for 10 min at 4°C. Pellet was allowed to dry on the bench or using a Speed-Vac and dissolved in 100  $\mu$ L TE buffer. One  $\mu$ L was used for subsequent analyses (e.g. PCR).

#### 1X CTAB Buffer for DNA preparation

1.4 M NaCl

100 mM Tris-HCl, pH 8.0

2% (w/v) CTAB

20 mM EDTA, pH 8.0

1% (w/v) polyvinylpyrrolidone, Mr 40,000 (Sigma PVP-40 or P-0930)

#### 2.2.3.2 Genomic DNA preparation for Southern blotting using DNeasy Plant Mini Kit

Genomic DNA used for Southern blotting was isolated using DNeasy Plant Mini Kit (Qiagen, Hilden, Germany). Leaf (or root) material was ground and 100 mg powder were weighed and used for DNA extraction according to the manufacturer's protocol. The concentration and purity of DNA was measured using spectrophotometer (Method 2.2.3.6).

#### 2.2.3.3 Plasmid DNA preparation

Plasmid DNA were prepared with the help of Qiaprep<sup>®</sup> Spin Miniprep Kit (Qiagen, Hilden, Germany), according to the manufacturers protocol. Up to 20  $\mu$ g of high copy plasmid DNA could be obtained from 1 to 5 mL overnight cultures of bacteria in LB medium.

#### 2.2.3.4 Isolation of total RNA for RT-PCR

An RNA isolation protocol particularly well suitable for samples rich in polyphenolics or polysaccharides was used in this study (Chang et al., 1993). This method is very effective for isolation of total RNA from a wide range of samples and was therefore applied for isolation of whole RNA. About 100 mg of liquid nitrogen frozen or fresh material were ground to the very fine powder with a mortar and pestle under liquid nitrogen, transferred to a 2 mL Eppendorf tube and 500  $\mu$ L of 65° C pre-warmed extraction buffer (490  $\mu$ L CTAB-Buffer + 10 $\mu$ L 2-Mercaptoethanol) were then added. Samples were vortexed thoroughly and total RNA was extracted by addition of 500  $\mu$ L chloroform/isoamylalcohol (24:1) followed by a centrifugation at 10 000 rpm for 5 min. This step was repeated once to increase the purity of the RNA sample. The supernatant was then transferred to an Eppendorf tube and total RNA precipitated overnight at 4° C by addition of 1/4 volume of 10 M Lithium chloride. Samples were then centrifuged at 14 000 rpm for 20 min at 4° C and pellet resuspended in 500  $\mu$ L of SSTE buffer and incubated at room temperature for 2 h with agitation. After a new extraction with 500  $\mu$ L chloroform/isoamylalcohol (24:1), the supernatant was transferred to a fresh Eppendorf tube and 1/10 Volume of 3 M Sodium-Acetate (NaOAc, pH 5.2) and 2 volume of absolute ethanol p.a. was added (or 1 volume of isopropanol in case of large volume). After 20 min at -20° C samples were centrifuged at 14 000 rpm for 20 min at 4° C, washed with 75% ethanol p.a. and centrifuged as above. Pellet were then allowed to dry on the bench and resuspended with 500  $\mu$ L of TM buffer. Any traces of DNA were removed by addition of 1  $\mu$ L DNase and incubation at 37° C for 15 min. DNase was then extracted by addition of 500  $\mu$ L chloroform/isoamylalcohol (24:1); samples were centrifuged and RNA precipitated by addition of 1/10 Volume of 3 M Sodium-Acetate (pH 5.2) and 2 volume of absolute ethanol p.a. and incubation for 30 min at -20° C. After centrifugation and washing by 75% ethanol as mentioned above, pellet was allowed to dry and resuspended in 20  $\mu$ L DEPC-treated sterile water. Quality and concentration of RNA samples were than assessed by measuring the absorption at 260 nm in a spectrophotometer and integrity was analyzed in a 1% agarose gel electrophoresis (Methods 2.2.3.6 and 2.2.4.4).

#### CTAB RNA Extraction buffer

2 % CTAB

2 % PVP K30

100 mM Tris/HCl pH 8.0

25 mM EDTA

2 M NaCl  
0,5 g/l Spermidine

#### SSTE Buffer

1 M NaCl  
0,5 % SDS  
10 mM Tris/HCl pH 8,0  
1 mM EDTA

#### TM Buffer

40 mM Tris/HCl pH 7.5  
6 mM MgCl<sub>2</sub>

#### **2.2.3.5 Isolation of total RNA using Qiagen RNeasy Plant Mini Kit**

For isolation of Total RNA to be used for Affymetrix ATH1 microarray hybridization, RNeasy Plant Mini Kit (Qiagen, Hilden, Germany) was used. 100 mg leaf (or root) powder was weighed and RNA was extracted according to the manufacturer's protocol.

#### **2.2.3.6 Determination of nucleic acids concentration**

The concentration of DNA or RNA was determined by measuring the absorption at 260 nm and 280 nm. 10 mM Tris/HCl pH 7.5 was used to zero the spectrophotometer (Nanodrop ND-1000, Kisker-biotech, Germany). The ratio A<sub>260</sub>/A<sub>280</sub> was calculated to estimate the purity of total DNA or RNA with respect to contaminants that absorb in the UV (e.g. proteins absorb at 280 nm). The ratio of isolated DNA (RNA) was about 1.8 (2.0) indicating high quality DNA (RNA). The integrity of RNA was then check in 1% agarose gel electrophoresis (Method 2.2.4.4).

### **2.2.4 Molecular biology methods**

#### **2.2.4.1 PCR (Polymerase Chain Reaction)**

The purpose of a PCR is to make a big number of copies of a DNA fragment which can then be subsequently used (e.g. for sequencing or DNA cloning). There are three major steps in a PCR, which are repeated for 30 to 40 cycles. It starts with a denaturation step that occurs at high temperature (95°C) and during which the double strand melts, open to single stranded DNA and all enzymatic reactions stop. It is followed by annealing step at lower temperature

which depends on primer sequence. The primers bind to complementary sequence of the template and the polymerase can attach and starts copying the template. Once there are a few bases built in, the base pairing is so strong between the template and the primer, that it does not break anymore. The final step is the extension step at 72°C (ideal working temperature for the polymerase). The bases (complementary to the template) are coupled to the primer on the 3' side, polymerase adds dNTPs from 5' to 3', reading the template from 3' to 5' side, and bases are added complementary to the template.

PCR mix was prepared as followed:

- Template DNA (e.g. 1 µL from CTAB DNA preparation, 20 ng plasmid DNA)
- 2 µL of 10X reaction buffer
- 0.2 µL 20 mM dNTPs
- 1 µL of 10 µM forward primer
- 1 µL of 10 µM reverse primer
- 0.1 µL (5 U/ µL) of Taq polymerase (Q-Biogen)
- Sterile ddH<sub>2</sub>O to an end volume of 20 µL

PCR was performed in an automated Multicycler PTC-200 (Biozym, Germany) as followed:

- 95°C	2 min	1 cycle
- 95°C	30 sec	} 30-40 cycles
- X°C (annealing)	30 sec	
- 72°C	1 min/1kb	
- 72°C	5 to 7 min	
- 4°C	∞	

PCR products were then separated and visualized on agarose gel (Method 2.2.4.5).

#### 2.2.4.2 Reverse Transcription Polymerase Chain Reaction (RT-PCR)

To analyze the transcript presence in the *pip2* mutants, total RNA was extracted from *Arabidopsis* tissues (Method 2.2.3.4) and used to synthesize cDNA. One µg total RNA was added to a cocktail containing 1X first-strand-synthesis buffer (Invitrogen, Germany), 1 mM dNTP Mix (MBI fermentas, Germany), 0.01 M DTT, 20 units RNase Inhibitor (MBI Fermentas, Germany), 3.5 µL of 0.05 µg/µL oligo (dT)<sub>12-18</sub> (Invitrogen, Germany) and DEPC-treated water to a final volume of 20 µL. After a 10 min incubation at room temperature 1 µL Reverse transcriptase Superscript II (diluted 1:3 in 1X first-strand-synthesis buffer, 67 U; Invitrogen, Germany) was added. The cDNA was then synthesized

using the following temperature scheme in PCR machine:

- 42°C 30 min
- 50°C 40 min
- 95°C 5 min
- cool down to 4°C.

As a control for genomic DNA contamination, a reaction without Reverse transcriptase was performed in parallel. A PCR reaction (Method 2.2.4.1) was then performed in a Multicycler PTC-200 (Biozym, Germany) using 1 to 2  $\mu$ L cDNA and gene specific primers. Polymerized fragments were then separated and visualized on agarose gel (Method 2.2.4.5).

#### **2.2.4.3 Purification of PCR product and DNA gel extraction**

After PCR reaction or other enzymatic reactions, DNA fragments were purified from primers, nucleotides, polymerases and salts. The purification was performed with Qiaquick<sup>®</sup> PCR Purification Kit (Qiagen, Hilden, Germany) following manufacturer's instructions.

To purify or extract target DNA fragment from unspecific fragments from standard or low melting agarose Qiaquick<sup>®</sup> Gel Extraction Kit (Qiagen, Hilden, Germany) was applied according to the manufacturer's protocol. The method was appropriate for extraction and purification of DNA of 70 bp to 10 kb.

#### **2.2.4.4 Digestion by restriction endonucleases**

To check the length of insert in plasmid, the plasmid was cleaved by restriction endonucleases. Restriction endonucleases were chosen depending on the sequence of nucleic acid that insert was flanked. Digest contained about 0.5  $\mu$ g plasmid DNA, 1X reaction buffer, ca. 5 units of restriction endonuclease(s), ddH<sub>2</sub>O was added to the volume up to 20  $\mu$ L. The mixture was incubated at 37°C for about 2-3h. The enzyme(s) was (were) deactivated at 65°C for 10 min. The fragments sizes were checked by agarose gel electrophoresis (Method 2.2.4.5).

#### **2.2.4.5 Separation and visualization of nucleic acids on agarose gel electrophoresis**

Nucleic acids were separated on agarose gel (0.5 to 2% in 1X TAE buffer) according to size of nucleic acids. It was added 0.5  $\mu$ g/mL ethidium bromide (nucleic acids staining) to the agarose gel prior allowing it to polymerize. Nucleic acid samples were mixed with 5X DNA loading buffer. The samples as well as DNA standard marker were then loaded in the gel and

run at 5-10 V/cm for 1 to 2 h. DNA fragments were visualized under UV light and recorded with Bio-Rad Gel Doc 2000 (Bio-Rad, Munich, Germany).

The integrity and size distribution of total RNA was checked by 1% agarose gel electrophoresis and ethidium bromide staining. The respective ribosomal bands appeared as sharp bands on the stained gel.

#### 2.2.4.6 Molecular cloning using the Gateway recombination technology

DNA fragments encoding different PIP2 promoters, PIP2-promoter-Open Reading Frame or PIP2 epitopes were polymerized by PCR using forward and reverse primers containing 29mer attachments allowing recombination according to the Gateway® Technology (Invitrogen, Germany). PCR were performed using the Pfu-Turbo proof-reading polymerase according to the manufacturer's recommendations (Stratagene, Germany). Two recombination reactions constitute the basis of the Gateway® Technology (Fig. 5). PCR fragments were first recombined by mean of the BP recombination in a 5 µL reaction (1/4 the recommended volume) into a vector pDONR221 (Fig. 5a). In this new vector, the integrity of the insert was confirmed by sequencing. This new vector carrying the insert is then used for the second recombination (LR recombination) to transfer the insert into the final destination vector. Destination vectors are binary vector allowing the transfer of the T-DNA into *Agrobacterium tumefaciens* (Method 2.2.2.3) and the subsequent transformation of *Arabidopsis thaliana* plants by the floral dip method (Method 2.2.2.4).

This cloning procedure was used to generate transgenic plants expressing β-glucuronidase (GUS) reporter gene under the control of different PIP2 promoters. *PIP2;1*, *PIP2;2*, *PIP2;3* and *PIP2;4* have been analyzed in the past in our group using such promoter::GUS fusion constructs (Franck, 1999). In addition, seeds of transgenic plants expressing a *PIP2;5* promoter::GUS fusion protein were kindly provided by Dr. Ulrich Hammes (Molekulare Pflanzenphysiologie, FAU Erlangen) (Hammes et al., 2005). Consequently, constructs were generated for *PIP2;6*, *PIP2;7* and *PIP2;8*. The promoter of *PIP2;6*, *PIP2;7* and *PIP2;8* were fused to the GUS gene and transferred into *Arabidopsis* plants. Since constructs previously made were in *Arabidopsis thaliana* ecotype C24 background whereas the *PIP2;5* promoter::GUS line was introduced in *Arabidopsis thaliana* ecotype Col0, the new *PIP2* promoter::GUS constructs were introduced into both Col0 and C24 ecotype.

Promoter regions of *PIP2;6*, *PIP2;7* and *PIP2;8* were isolated by PCR. DNA fragments containing about 2.5 kb of the 5' upstream region of the corresponding *PIP2* coding sequence were amplified using a proof-reading polymerase and forward and reverse primers allowing

recombination according to the Gateway system. The polymerized promoter regions were then inserted into pDONR221 transformation vectors (which allow reporter translational fusion constructs with GFP-GUS under the control of the *PIP2* promoter) by mean of a BP recombination (Fig. 5a). This new vector was then used for the second recombination (LR recombination) to transfer the insert upstream the GFP/GUS sequence within the T-DNA of the destination vector pBGWFS7 (Fig. 5b). The resulting construct was then transferred into *Arabidopsis thaliana* plants.

**Figure 5. Schematic representation of *PIP2* promoter::GUS constructs using the Gateway technology.**

(a) BP recombination into the entry vector pDONR221. (b) LR recombination into the destination vector pBGWFS7. In case of the promoter-ORF-GFP fusion constructs for *PIP2;1* and *PIP2;4*, the destination vector pK7FWG2 was used. LB: T-DNA left border; RB: T-DNA right border.

In case of *PIP2;1* and *PIP2;4* a promoter-ORF-GFP fusion construct has also been introduced into *Arabidopsis thaliana* ecotype Col-0 (as well as in a *pip2;1* knockout mutant for *PIP2;1*). Transgenic plants expressing these fusion proteins were generated in a way similar to that of *PIP2* Promoter::GUS constructs. However, the stop codon of *PIP2;1* (or *PIP2;4*) was modified to allow simultaneous expression of our gene of interest and the GFP. In both *PIP2;1* and *PIP2;4* constructs, the inserts had been verified by sequencing after recombination/cloning into the entry vector pDONR221. The destination vector pK7FWG2 used for *AtPIP2*-promotor-ORF\_GFP fusion construct (Karimi et al., 2002) allows translational fusion of ORFs with the coding sequence of GFP under the control of CaMV 35S promoter. However, in the present study, the 35S-promoter was released by digestion of the vector, using the unique, flanking restriction sites SpeI and SacI, and religation. The resulting, derivative vector, pK7FWG2Δ35S, has been checked by restriction analysis and sequencing.

In case of PIP2 epitopes, the insert was transferred into destination vector pDEST15 allowing the expression as a GST fusion protein in *E. coli*.

#### 2.2.4.7 DNA sequencing

Samples (e.g. PCR products, Plasmid DNA) for sequencing were prepared according to manufacturer's instructions and processed either by Medigenomix GmbH (Martinsried, Germany) or AGOWA GmbH (Berlin, Germany).

#### 2.2.4.8 Southern blotting

Genomic DNA to be used for Southern blotting was extracted using DNeasy Plant Mini Kit (Qiagen, Hilden, Germany; Method 2.2.3.2).

Genomic DNA (2 µg) extracted from *Arabidopsis thaliana pip2* mutant was digested in a reaction volume of 300 µL with 30 to 40 U of restriction enzyme by incubation at 37°C for 12 to 16 h (overnight). After phenolization (300 µL roti-Phenol/Chloroform/Isoamylalcohol, 25/24/1, Roth Carl GmbH, Karlsruhe, Germany), DNA in upper phase was transferred to a fresh eppendorf tube containing 1 µL 1% LPA. DNA was then precipitated by 2.5 volume of ethanol p.a. and 1/10 volume of NaOAc 3 M and placed at -80°C for 1 h. After centrifugation at 14 000 rpm, 4°C for 20 min, DNA pellet was washed with 750 µL 75% ethanol p.a., dried and resuspended in 20 µL TE-buffer, pH 8.0 and 5 µL 5X gel loading buffer. Digests of *Arabidopsis thaliana* wild-type col-0 DNA were always included as an internal control.

To quickly check for complete digestion and confirming the amount of DNA, 1/5 of the digests were run on a small 0.7% agarose gel for 1 h. Although not well separated, a characteristic pattern due to repetitive DNA and the organellar DNA content could be visible. The remaining digests were then separated on a 0.7% agarose gel containing 0.5 µg/mL ethidium bromide in 1X TAE buffer. The electrophoretic separation was carried out at around 5 V/cm in a cold room (4°C) overnight (about 20 h). Additional lanes with Lambda DNA/Eco91I (BstEII; MBI Fermentas, Germany) digest were included as a size marker: 1 lane containing about 700 ng which are visible after UV illumination and additional lanes with about 2 ng directly adjacent to the lanes with the genomic DNA sample digests. After the gel has run completely, it was visualized under UV light and photographed with Bio-Rad Gel Doc 2000 (Bio-Rad, Munich, Germany). Unused lanes and extra of the gel were excised as well as the lane containing 700 ng of λ-DNA.

After visualization, a piece of positively charged nylon membrane (Hybond-N<sup>+</sup>, Amersham, Germany) was cut according to the size of the gel and soaked with 0.4M NaOH. DNA was transferred onto the nylon membrane by alkaline transfer with a vacuum blotting chamber (VacuGene-XL, Pharmacia, Germany) according to manufacturer's protocol. The transfer was carried out for 1h 40 min at 40 cm H<sub>2</sub>O with 0.4M NaOH. The gel was then removed and the membrane washed and neutralized in 2X SSC buffer. With a positively charged nylon membrane, the transferred DNA is covalently linked to the membrane if an alkaline transfer buffer is used. Therefore DNA immobilization by baking or UV crosslinking was not needed. The membrane was dried, wrapped in plastic wrap and stored at 4°C (-20°C for long storage) until processed.

To block unspecific binding sites on the membrane, it was prehybridized for 4h at 68°C with 1 mL/20 cm<sup>2</sup> prehybridization buffer (see method 2.2.8 for pre-hybridization solution).

DNA probes were prepared by PCR amplification of a part of the T-DNA left border of Gabi, Sail, Salk and SM insertion lines (For primers see Annex 1). DNA probe were then radioactively labeled with [ $\alpha$ -<sup>33</sup>P]dATP (>2500 Ci/mmol). Labeling was performed using 40 ng DNA probes with Strip-EZ<sup>®</sup> DNA kit (Ambion, USA) according to manufacturer's instructions. However, reverse and forward primers were used with their corresponding probe instead of decamers. Lambda DNA/Eco91I was labeled in a similar way using 25 ng DNA and decamers. The labeling reaction was carried out for 1h at 37°C and was stopped by addition of 1 µL 0.5 M EDTA (pH 8.0). The labeled probes were diluted by addition of 75 µL water and purified by spinning through S400-HR MicroSpin column (Amersham, Germany). The incorporation was estimated by measuring radioactivity before (total radioactivity) and

after purification (incorporated radioactivity). If less than 30% were incorporated, a new labeling procedure was done. For hybridization, labeled probes were denatured by boiling at 95°C for 5 min and immediate chilling in ice-water. After about 3 min denatured probes were added to the prehybridization solution (in case of Lambda DNA/Eco91I, only 1/4 of the labeled probe was added to each membrane). Hybridization was carried out at 68°C for about 20 hours. Membranes were then rinsed once with 2X SSC, 0.1% SDS prewarmed to about 68°C. Unspecifically bound probes were then removed by washing once with 2X SSC, 0.1% SDS for 15 min at 68°C followed by two washes with 0.2X SSC, 0.1% SDS at the same conditions. Membranes were then placed over a Whatman paper (prewet in 2X SSC), wrapped into plastic wrap and exposed with DNA side facing a Fuji imaging plate. Exposure was performed for about 24h and hybridization signals were revealed by scanning the membrane using FLA3000 image reader (Fuji, Düsseldorf, Germany).

### 2.2.5 Isolation and molecular characterization of *pip2* T-DNA insertional mutants

Informations about *AtPIP2* insertional mutant candidates were obtained by screening the publicly accessible SIGNAL T-DNA Express database of the SALK institute (<http://signal.salk.edu/cgi-bin/tdnaexpress>). Mutant candidates from various sources were retrieved; i.e. from the SALK (Alonso et al., 2003), the GABI-Kat (Rosso et al., 2003), the SM (Tissier et al., 1999), the Genoplante FLAGdb/FST (Balzergue et al., 2001) and the SAIL collections (Sessions et al., 2002). The seeds were purchased from the Nottingham *Arabidopsis* Stock Center (NASC) or from the *Arabidopsis* Biological Resource Center (ABRC, Ohio state University, USA, <http://www.biosci.ohio-state.edu/pcmb/Facilities/abrc/abrchome.htm>). GABI lines and FLAG lines were purchased from GABI-Kat (MPI, Köln, Germany) and the Institut National de la Recherche Agronomique (INRA, Versailles, France), respectively.

Insertional mutant candidate lines were first screened by PCR analysis using a combination of primers specific for the corresponding *PIP2* gene and for the T-DNA left border sequences, respectively. Since the orientation of the insertions were not known, a reverse and forward primer specific for the *PIP2* genes were used in combination with primer specific for the T-DNA left border (see Annex 1 for primers). In addition, to reveal homozygous mutants (i.e. insertion in both alleles) the integrity of the *PIP2* coding sequence was then probed using *PIP2* gene-specific primers flanking the predicted T-DNA insertion sites. In our PCR conditions (Methods 2.2.4.1), the presence between the two gene-specific primers of a T-DNA or transposon insertion should prevent any DNA amplification. Consequently, the gene-

specific primer combination generated a product from the wild-type gene in wild-type and heterozygous plants but not in homozygous plants. To verify PCR products and identify T-DNA insertion sites, all amplified products were sequenced.

Homozygous mutants were further analyzed by RT-PCR to check whether homologous mutations in *pip2* mutants resulted in loss of transcripts (Method 2.2.4.2).

Insertional mutants isolated and characterized in this work are listed in table 1.

## 2.2.6 Protein methods

### 2.2.6.1 Preparation of microsomal fractions from *Arabidopsis thaliana* tissues

To avoid protein degradation, every step until resuspension was done in a cold room (4°C). Mortar, pestle as well as centrifuge and ultracentrifuge tubes were pre-cooled at 4°C before use. About 0.5 to 1 g plant material (roots or leaves) were ground to a fine powder and mixed with 8 mL homogenization buffer. The homogenate was filtered through 2 layers of miracloth into pre-chilled centrifuge beaker (SS-34). Mortar was washed with 2 mL homogenization buffer which were filtered as well and added to the homogenate for a final volume of 10 mL. After centrifugation at 8000g for 10 min at 4°C (Sorvall RC 5B+), the supernatant was filtered through a layer of miracloth into Beckman-ultra-clear tubes (for rotor SW 28) and centrifuged at 110 000 g for 40 min at 4°C (Ultracentrifuge LE-70). The supernatant was discarded and 100 µL of resuspension buffer was added to the pellet. The pellet was then incubated on ice for 30 min. The pellet was resuspended using a douncer after addition of 200 µL resuspension buffer. Microsomal fractions were thereafter transferred into a fresh eppendorf tube and stored at -80°C.

#### Homogenization buffer

- 50 mM Hepes-KOH pH 7.5
- 5 mM EDTA pH 8.0
- 1 mM PMSF (freshly added)
- 0.1 mg/mL BHT
- 2 mM DTT (freshly added)
- 0.1% PVPP (freshly added)
- 0.5 M sucrose

#### Resuspension buffer

- 0.33 M sucrose

5 mM K<sub>3</sub>PO<sub>4</sub> pH 7.8  
4 mM KCl  
2 mM DTT  
ddH<sub>2</sub>O

### 2.2.6.2 Protein isolation from *E. coli*

One mL culture of transformed *E. coli* BL21 (DE3) were grown on 100 mL LB medium containing 100 µg/mL ampicillin at 37°C, 250 rpm until OD<sub>600</sub> = 0.6. For induction of protein synthesis, 0.1 mM IPTG was added in the medium and it was then incubated for 3h, centrifuged at 9000 g for 10 min at 4°C and pellet was then frozen in liquid nitrogen and stored at -80°C until isolation of GST-fusion proteins. Bacterial pellet was resuspended in 2.5 mL homogenization buffer 1 and incubated at room temperature for 15 min with gentle shaking. Cells were lysed by addition of 3 mL homogenization buffer 2 with 1% Triton X-100 and 15 min incubation at room temperature with shaking. Cell lysate was then centrifuged at 15 000 rpm for 10 min at 4°C and supernatant was collected.

#### Homogenization buffer 1

25 mL Bugbuster™ HT protein  
25 µL 2-Mercaptoethanol  
500 µL Lysozym (0.5 mg/ 50 µL in 0.1 M Tris/HCl pH 8.0)  
125 µL Complete protease inhibitor cocktail (Roche, Mannheim, Germany)

#### Homogenization buffer 2

30 mL 1X PBS  
30 µL 2-Mercaptoethanol

### 2.2.6.3 Purification of GST-fusion protein

A 300 µL aliquot of Glutathione Sepharose™ 4B (Amersham, Germany) equilibrated by 1X PBS was added into the supernatant and shaken at room temperature for 30 min, centrifuged at less than 1000 rpm for 5 sec to pellet Glutathione Sepharose™ 4B beads. Supernatant was discarded and pellet transferred to column. After 3 washes with 1X PBS, fusion proteins were eluted by addition of two times 300 µL Glutathione (20 mg/ 3 mL in 0.1 M Tris/HCl pH 8.0).

#### 2.2.6.4 GST-fusion protein activity assay

The following solutions 10  $\mu\text{L}$  of 100 mM 1-Chloro-2,4-Dinitrobenzene (CNDB), 100  $\mu\text{L}$   $\text{KH}_2\text{PO}_4$  pH 6.5, 10  $\mu\text{L}$  100 mM Glutathione and 880  $\mu\text{L}$  double distilled were mixed in two cuvette labeled by blank and sample. The two cuvettes were mixed and 55  $\mu\text{L}$  of the sample (supernatant or eluate) was added into sample cuvette and mixed. Absorbance at 340 nm was recorded at 1 min interval for 5 min by first blanking the spectrophotometer. The activity of GST (glutathione S-transferase) was calculated as  $A_{340 \text{ nm}}/\text{min}/\text{mL}$ .

#### 2.2.6.5 Determination of protein concentration using Bradford method

800  $\mu\text{L}$  samples containing 2.5 to 20  $\mu\text{g}$  BSA in 0.1 M Tris/HCl pH 8.0 were mixed with 1X Bradford solution, incubated at room temperature for 15 min and absorbance at 595 nm was measured.

#### 2.2.6.6 ESEN test for determination of protein concentration

The protein content of the microsomal fractions was precisely determined using the Esen test (Esen, 1978). This test is based on the protein coloration by Coomassie brilliant Blue. It measures the protein concentration in their denatured form and do not need any further preparation and can therefore be immediately used for a SDS-polyacrylamide gel electrophoresis. This assay is specific for proteins and virtually free from interference by common laboratory reagents and other nonproteinaceous substances.

The microsomal fractions were prepared by adding, on ice, the following to 90  $\mu\text{L}$  microsomal fractions:

15  $\mu\text{L}$  1M DTT (final concentration 0.1M)

15  $\mu\text{L}$  20% SDS

30  $\mu\text{L}$  5X Laemmli buffer (Laemmli, 1970) (without Bromophenol Blue) + 1.5  $\mu\text{L}$  2-mercaptoethanol freshly added

Similarly, BSA standard solutions of 0.2  $\mu\text{g}/\mu\text{L}$ , 0.5  $\mu\text{g}/\mu\text{L}$ , 0.75  $\mu\text{g}/\mu\text{L}$  and 1  $\mu\text{g}/\mu\text{L}$  were prepared with similar final concentration of DTT, SDS and Laemmli buffer.

Microsomal fractions as well as standard solutions were then denatured for 20 min at 56°C, centrifuged for 2 min at 15300 rpm and supernatants transferred into a fresh 1.5 mL Eppendorf tube. Proteins were then spotted on a 1 cm x 2 cm Whatman paper; 10  $\mu\text{L}$  of protein solution were spotted in two neighboring spots of 5  $\mu\text{L}$  each and allowed to dry for 5 min. A sample without protein was used as a control. Whatman papers containing the protein were then incubated for 5 min in fixation solution (25% (v/v) Isopropanol and 10% (v/v)

Glacial acetic acid) followed by 15 min incubation in coloration solution (0.1% (w/v) Coomassie brilliant Blue R250 in fixation solution), both under agitation. After destaining with water (boiled in microwave) and drying, the stained spots are cut, placed in a 2 mL Eppendorf tube and the dye-protein complex is eluted in 1.5 mL 0.5% SDS. Samples were incubated 1 h at 56°C (or overnight at room temperature). Protein concentration was determined by measuring the absorbance at 578 nm. The control sample was used as a blank. The protein concentration usually ranged between 0.25 and 0.5 µg/µL.

#### **2.2.6.7 SDS polyacrylamide Gel Electrophoresis (SDS-PAGE)**

This gel system uses the method described by Laemmli (1970). The protein sample is denatured and coated with detergent by heating in the presence of SDS and a reducing agent. The SDS coating gives the protein a high net negative charge that is proportional to the length of the polypeptide chain. The sample is separated on a polyacrylamide gel containing SDS by electrophoresis. Since a net negative charge taken by proteins is roughly proportional to their size, the molecular mass of the proteins can be estimated by comparing the mobility of a band with protein standards.

Electrophoretic separation was done using an Amersham biosciences Mighty Small II unit for 8 x 7 cm gels with a thickness of about 0.75 mm. The separating gel consisted of 12% acrylamide and 10% ammonium persulfate and TEMED were added just prior to pouring the gel. The resolving gel mix was poured into assembled plates, leaving sufficient space at the top for the stacking gel to be added later. The top was layered with water saturated butanol and allowed to polymerize at room temperature for about half an hour. Then the 6% stacking gel was poured after removing the butanol and rinsing the surface. The appropriate combs were fixed and the gel allowed to polymerize. At least 1 cm of stacking gel should be present between the bottom of the loading wells and the resolving gel. 1X SDS-PAGE running buffer was poured into the apparatus till the top of the wells.

Microsomal fractions (2 or 5 µg, for PIP1 or PIP2 blot, respectively) were denatured at 56°C for 20 min. Since all loading reagents (Laemmli buffer, SDS and 0.1M DTT) were added during protein determination by ESEN, no further reagents had to be added and samples were simply denatured at 56°C for 20 min. Under these conditions, PIP1 and PIP2 aquaporins run mostly as monomers of 28-30 kDa. The denatured protein samples were then loaded onto the gel as well as a prestained protein standard marker (Broad range, 6-175 kDa, New England Biolabs, also denatured similarly as for the microsomal fractions). Electrophoresis was carried

out initially at 80V until the dye front reached the separating gel. Subsequently, electrophoresis was continued at 100V till completion.

SDS-polyacrylamide gel electrophoresis buffers:

4X separate buffer

1.5 M Tris/HCl pH 8.8

0.4% (w/v) SDS

4X stock buffer

5 M Tris/HCl pH 6.8

0.4% (w/v) SDS

12% separating gel (10 mL)

ddH<sub>2</sub>O 3.350 mL

4X separate buffer pH 8.8 2.5 mL

30% acrylamide (Rotiphorese) 4.0 mL

10% Ammonium persulfate 50 µL

TEMED 5 µL

6% Stacking gel (5 mL)

ddH<sub>2</sub>O 2.5 mL

4X stock buffer pH 6.8 1.25 mL

30% acrylamide (Rotiphorese) 1.0 mL

10% Ammonium persulfate 40 µL

TEMED 20 µL

1X Running buffer

0.025 M Tris, pH 8.3

0.192 M glycine

SDS 0.1%

ddH<sub>2</sub>O

5X Laemmli buffer (Laemmli, 1970)

10% (w/v) SDS

30% (v/v) glycerol  
100 mM Tris/HCl pH 6.8  
5% (v/v) 2-mercaptoethanol (add fresh)  
(Optionally 0.1% bromophenolblue)

#### Prestained Protein Marker, Broad Range (6-175 kDa)

MBP- $\beta$ -galactosidase, 175 kDa  
MBP-paramyosin, 83 kDa  
Glutamic dehydrogenase, 62 kDa  
Aldolase, 47.5 kDa  
Triosephosphate isomerase, 32.5 kDa  
 $\beta$ -Lactoglobulin A, 25 kDa  
Lysozyme, 16.5 kDa  
Aprotinin, 6.5 kDa

#### **2.2.6.8 Staining of SDS-PAG with Coomassie Brilliant blue**

To visualize the proteins on the SDS-PAG, it was stained 2 h to overnight with a Coomassie dye solution (0.05% Coomassie R-250, 50% methanol, 10% acetic acid) and destained in destaining solution (10% methanol, 10% acetic acid). The bands were visualized as blue bands, photographed and documented with Bio-Rad Gel Doc 2000 (Bio-Rad, Munich, Germany).

#### **2.2.6.9 Western blot**

Protein transfer onto PVDF membrane was done using a semi-dry transfer unit (Milliblot-Graphite Electrobloetter I, Millipore, USA). The transfer unit was rinsed with transfer buffer. The stacking gel was removed and the size of the separating gel was measured. The PVDF membrane and 9 blotter sheets (Whatman-3MM paper) were cut to the same size as the gel. They were pre-wet in transfer buffer. Six sheets of presoaked blotting paper were placed first, then the PVDF membrane, then the gel and finally 3 more buffer saturated blotter paper. At each step care was taken to remove air bubbles with a pipette by rolling over the sandwich. The transfer was carried out for 60 min according to the size of the gel (2.5 mA per cm<sup>2</sup>). To check the efficiency of the transfer the gel was stained with Coomassie brilliant blue solution (see above).

After blotting the PVDF membrane could be stained or used for immunological visualization of proteins. The PVDF membrane was immersed in the blocking solution and incubated at room temperature for 3 hours to overnight with gentle shaking. It was then washed once with TTBS for 10 min. After decanting the TTBS, the primary antibody in antibody buffer was added. A 1:1000 dilution was used for rabbit anti-PIP2 antiserum and a 1:3000 dilution was used in the case of rabbit anti-PIP1 antiserum. It was incubated for 2 hr at room temperature (or overnight at 4°C). Unbound antibody was removed by washing twice for 5 min each with TTBS. An anti-rabbit cy5-linked secondary antibody in antibody buffer was added (1:1000) and incubated for 1 hr. The conjugate solution was decanted and the membrane was washed twice for 5 min each with TTBS at room temperature. It was given a final wash with TBS and then ddH<sub>2</sub>O and membrane was scanned at 635 nm (Cy5 detection) using a FLA3000 image reader (Fuji, Düsseldorf, Germany). For quantification of the immunoblot signal, the intensity of each band was corrected for background and measured using ImageJ software (version 1.37v; <http://rsb.info.nih.gov/ij/>).

#### Transfer buffer

- 80% 1X running buffer
- 20% Methanol

#### Tris buffered saline (1X TBS)

- 10 mM Tris/HCl pH 7.5
- 150 mM NaCl

#### Wash solution (1X TTBS)

- 0.05% of Tween 20 in 1X TBS (10µl of Tween 20 + 20mL of TBS).

#### Blocking solution

- 2% Milk powder
- 1% BSA (Fraction V, Boehringer Mannheim)
- 1X TTBS to 100 mL

#### Antibody buffer

- 0.1% Milk powder
- 1X TBS to 100 mL

### 2.2.7 GUS staining of *Arabidopsis thaliana* plants

In order to study the expression pattern of different PIP2 isoforms *in situ*, the histochemical localization of the bacterial  $\beta$ -glucuronidase gene (*uidA* or *gusA*) commonly referred to as GUS was assessed in transgenic plants expressing this reporter gene under the control of different *PIP2* promoters. The visualization of GUS activity was done using the histochemical GUS-Assay with X-Gluc as substrate (Jefferson et al., 1987). The GUS enzyme catalyses the cleavage of 5-Bromo-4-chloro-3-indolyl- $\beta$ -D-glucuronic acid (X-Gluc) (a colorless substrate), which undergoes a dimerization leading to a final insoluble blue precipitate known as dichloro-dibromoindigo (ClBr-indigo). The ability of ClBr-indigo to immediately precipitate upon formation was used to trace the location site of GUS activity under the control of different *PIP2* promoters, allowing thereby an analysis of tissue specific localization of gene expression. Treated/untreated plant material was harvested, vacuum-infiltrated with fixation solution and further incubated in fixation solution for 30 min at room temperature. Samples were washed three times with phosphate buffer (Na-phosphate, pH 7.0) and then vacuum-infiltrated with GUS staining solution and incubated in this staining solution overnight at 37 °C (a minimum volume of the staining solution was used). Samples were thereafter incubated in several changes of 70 % (v/v) ethanol solution at 80 °C until complete destaining of chlorophyll. The samples were finally submerged and stored in 70% (v/v) ethanol at 4°C. Photographs were taken to show the expression pattern of the *PIP2* genes in plants.

#### GUS-fixation solution

- 0.5% Formaldehyde
- 0.05 % Triton X 100
- 50 mM Na-phosphate, pH 7.0

#### GUS-staining solution

- 1 mM X-Gluc in DMSO
- 1 mM Potassiumhexacyanoferrat (II)
- 1 mM Potassiumhexacyanoferrat (III)
- 0.1 % Triton X 100
- 50 mM Na-phosphate, pH 7.0

## 2.2.8 Custom-made DNA array harboring transport-related genes

A DNA array harboring gene-specific probes was established with the collaboration of several laboratories within the priority program “Dynamics and Regulation of Plant Membrane Transport” (DFG-Schwerpunktprogramm 1108 "Dynamik und Regulation des pflanzlichen Membrantransportes"). It harbors about 500 known and putative membrane transporter genes (e.g. aquaporins, ABC transporters, and vATPases and cation channels). The complete list of genes represented on the array can be found in supplementary Table 1.

### 2.2.8.1 Construction of target DNA sequences and array production.

Gene-specific probes were produced by selecting 3'-UTR sequences. Target sequences were then amplified by PCR using specific primer pairs and genomic DNA. PCR products were verified by sequencing and specificity of gene targets was checked by BLAST analyses. After purification, PCR products were cloned into pGEM-T easy vector (Promega, Germany), amplified using flanking vector DNA sequences, concentrated using Multiscreen plates (Millipore, USA), resuspended in water and spotted in duplicate onto Hybond-N<sup>+</sup> nylon membranes (Amersham, Germany) using MicroGrid II Robot (400 µm pins, 10 repeats per spot to transfer sufficient amount of DNA; BioRobotics, Cambridge, UK). Eventually, the membranes consisted of 8 rows x 12 columns of 4 x 4 subgrids (Fig. 6).

After spotting the membranes are dried (air) and nucleic acids were UV-cross-linked to the membrane using regular, default program of a Stratalinker (UV-Stratalinker 240, Stratagene, USA). Membranes were denatured with 0.5 M NaOH/ 1.5 M NaCl soaked Whatman paper for 5 min, neutralized with 0.5 M Tris/HCl pH 7.5/ 1.5 M NaCl soaked Whatman paper and washed with 2 SSC several times for pH neutralization.

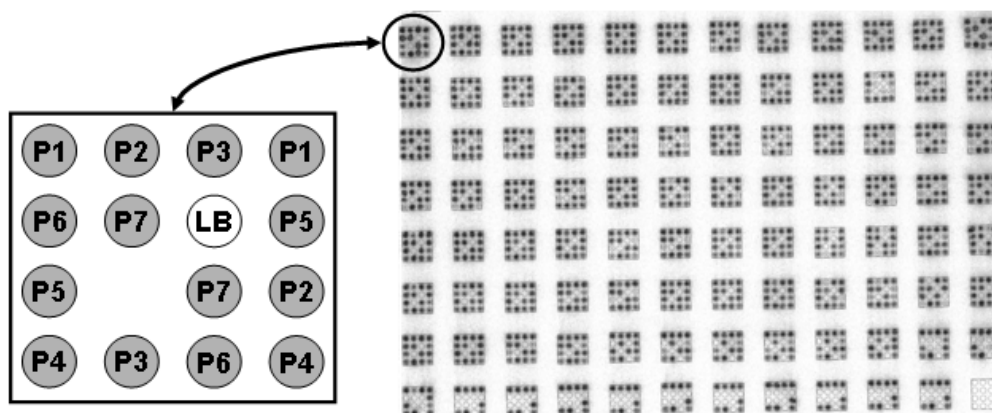

Before processing with reference hybridization, the membranes are incubated in 0.4 M NaOH at room temperature for 20 min on a shaker to remove non-fixed PCR products, neutralized in 2X SSC, blotted dry on a Whatman filter paper, air dried and stored at 4°C for further use.

### 2.2.8.2 Hybridization with T7 reference probes

Prior to hybridization with T7 oligonucleotides, the membranes were pre-hybridized at 42°C for 3 hours in 10 mL pre-hybridization solution containing 5X SSC, 5X Denhardt's solution, 0.5% SDS, 100 µg/mL denatured salmon sperm DNA (or Herring sperm). T7 Reference probes mixture were prepared and contained for each membrane 2.5 µL 10 µM T7 oligonucleotide (5'-GACTCACTATAGGGCGAATTG), 1.25 µL 10X polynucleotide kinase buffer A, 1 µL [ $\gamma$ -<sup>33</sup>P]ATP (2500 Ci/mmol, 10 µCi/µl; Amersham, UK), 1 µL T4

polynucleotide kinase (10 u/ $\mu$ L) and distilled water was added to a total volume of 12.5  $\mu$ L. The mixture was incubated at 37°C for 30 min and additional distilled water was added to the mixture to a total volume of 50  $\mu$ L. The non-incorporated nucleotides were removed by purification using MicroSpin G-25 Sephadex columns (Amersham, Germany) following manufacturer's protocol applying a total volume of 100  $\mu$ L. One  $\mu$ L T7 reference probe was then added to 10 mL scintillation solution and radioactive incorporation was measured by liquid scintillation counter (Beckman, USA). The calculated total activity of the eluate should be at least 10 to 15.10<sup>6</sup> cpm. Radiolabeled oligonucleotides were then added to the prehybridized filters in prehybridization solution. Hybridization was performed for about 20 h at 42°C. Filters were removed from hybridization solution, rinsed briefly with 2X SSC/0.1% SDS, then washed once in 2X SSC/0.1% SDS at 42°C for 30 min followed rinsing briefly in 0.2X SSC/0.1% SDS and a final wash in 0.2X SSC/0.1% SDS at 42°C for 30 min. The membranes were finally rinsed with 2X SSC, placed onto 2 sheets of 3MM Whatman paper soaked with 2X SSC and carefully wrapped into plastic film to prevent any drying during exposure. The membranes were then exposed to imaging plate (Fuji, Düsseldorf, Germany) for 3 hours and primary data were collected using a Fuji FLA 3000 image reader (Fuji, Düsseldorf, Germany).

Labeled probes were completely removed from filters by two washes with 0.4 M NaOH for 30 min. Membranes were completely neutralized by several washes with 2X SSC (until pH of the washing solution was less than 8), air dried and stored dry at 4°C until further use. Removal of the labeled probes was controlled by testing the radioactivity before and after with a hand-held monitor and by exposure (1 day) of the filters. Usually more than 95% should be removed and filters can be used for subsequent application.

**Figure 6. DNA array spotting scheme.**

Typical picture from a reference hybridization showing the distribution of probes on the DNA array (right panel) and representation of the spotting scheme on each 4 x 4 subgrid (left panel). Hybridization occurs with radioactive marked T7 oligonucleotide. P1 to P7 represent 7 microtiter plates. LB, Local Background.

### 2.2.8.3 Isolation of mRNA using Oligo(dT)25 Dynabeads and preparation of complex probes

For transcript analyses, mRNA was isolated from roots of 3-week-old hydroponically grown plants. For each genotypes (wild-type and twelve *pip2* mutants), roots of three independent biological replicates were grown and harvested in parallel and stored at -80°C prior to RNA isolation. To decrease biological variation each replicate represented about 10 individual plants. Isolation of root mRNA was done using Oligo(dT) Dynabeads (DynaL Biotech, Hamburg, Germany).

Beads were prepared by mixing original tube well, but gently. Gentle handling is important throughout the whole procedure to reduce shearing and mechanic forces. Hundred µL aliquots per reaction of the suspension were transferred into 1.5 mL RNase-free Eppendorf vials. Tubes were then placed into magnetic stand for 30 sec liquid removed by pipetting. After taking out the tube from the stand, 200 µL lysis buffer (with DTT) were added, beads resuspended and placed back into magnetic stand. Supernatant was removed and 200 µL Lysis buffer was added. At this stage, buffer is left in the tubes and removed just before addition of the plant lysate to prevent the beads from drying.

About 100 mg frozen root material was ground under liquid nitrogen to a fine powder. Frozen powder was then transferred into pre-cooled 2 mL Eppendorf tube and 1 mL lysis buffer was added and tube was quickly vortexed thoroughly to make sure that powder is “dissolved”. It was then centrifuged for 5 min, 15000 rpm, 4°C to remove cell debris. Beads were then separated from the lysis buffer on a magnet and supernatant discarded. Supernatant from the centrifuged samples (without any piece of tissue) was then added to the beads. It was then incubated for 5 min at RT by inverting several times the tubes. Tubes were placed into magnetic stand for approximately 30 sec until solution has cleared and supernatant were removed by pipetting; mRNA is hybridized to oligo(dT) covalently bound to the beads. Beads were washed twice with 800 µL washing buffer/LiDS/0.05% Tween 20. Beads were removed from the washing buffer using a PickPen<sup>®</sup> 1-M (pjk, Germany) and transferred into a fresh, RNase-free Eppendorf tube. Similarly, two washes using a Pick-Pen in 500 µL Washing buffer/0.05% SDS (but without LiDS) were done. Resuspended beads were divided into two portions which may be frozen in liquid nitrogen and stored at -80°C or used to proceed.

One portion of the beads was then used for cDNA synthesis. Beads were washed two times with 250 µL 1X Superscript buffer (self-made), transferred into fresh Eppendorf tube and resuspended in 100 µL superscript RT-Mix without Reverse Transcriptase Superscript II.

RT-Mix

- 20  $\mu$ L 5X RT buffer
- 1  $\mu$ L 100 mM DTT (10  $\mu$ L; 0,1 M)
- 25  $\mu$ L 2 mM dNTPs (2.5  $\mu$ L from 20 mM dNTP)
- 2.6  $\mu$ L RNase Inhibitor (40 U/ $\mu$ L)
- Add ddH<sub>2</sub>O to 98  $\mu$ L

Mix was preincubated at 42°C for 2 min; 2  $\mu$ L Superscript II (200 U/  $\mu$ L; Invitrogen, Germany) were added and samples were incubated at 42°C for 1 h and mixed by hand from time to time. Beads were separated on the magnetic stand and supernatant discarded. After two washes with 250  $\mu$ L RT Buffer/0.05 % Tween to remove protein and nucleotides, mRNA was eluted with 50  $\mu$ L Elution Buffer (TE, 10 mM Tris-EDTA, pH 8.5) by incubation for 2 min at 95°C and immediate separation of the beads on a magnet. Supernatant (mRNA) is transferred to a fresh Eppendorf tube. Elution step is repeated once and mRNA was stored at -80°C for further analyses.

Beads were washed twice with 250  $\mu$ L TE buffer (pH 8.5) and twice with water and [<sup>33</sup>P]-labeled cDNA probes were synthesized via random primed labeling using Strip-EZ<sup>®</sup> DNA kit (Ambion, USA) following manufacturer's instructions with slight modifications. Briefly, water was removed from beads as completely as possible and 14.0  $\mu$ L ddH<sub>2</sub>O, 4.0  $\mu$ L 10X Decamer solution were then added. After denaturing the beads 2 min at 95°C, the following solutions were added:

- 8  $\mu$ L 5X buffer without dATP, dCTP
- 4  $\mu$ L 10X modified dCTP
- 7  $\mu$ L [ $\alpha$ -<sup>33</sup>P]dATP (2500Ci/mmol, 10  $\mu$ Ci/ $\mu$ l; Amersham, UK)
- 3  $\mu$ L Exonuclease-free Klenow (5 u/ $\mu$ L)

Beads were then incubated for 2.5 h at 37°C and mixed every 10 to 15 min. Supernatant containing non-incorporated nucleotides was then removed by magnetic separation and diluted to a total volume of 500  $\mu$ L. A 2  $\mu$ L aliquot was added to 10 mL scintillation solution for scintillation counting.

The synthesized, labeled DNA strand is then eluted from the beads with 50  $\mu$ l elution buffer (10mM TE, pH 8.5) by incubating for 3 min at 95°C and collecting the supernatant containing the labeled DNA in a fresh Eppendorf tube as soon as possible after magnetic separation. This elution step was repeated once and the eluates were combined. The beads may be frozen and stored with TE and reused for new second strand synthesis.

The eluate was then purified by centrifugating over Whatman Anopore filter units (VWR, Germany) at 4000 rpm for 1 min and 2  $\mu$ L of the eluate were mixed with 10 mL of scintillation solution. After scintillation counting, labeling efficiency was calculated (about  $1.10^6$  cpm).

#### **2.2.8.4 Hybridization with complex probes and data acquisition**

Filters were placed into a bottle with the DNA side facing towards the inside of the bottle with 4 mL pre-hybridization solution per filter (Method 2.2.8.2) and pre-hybridized for at least 4 h at 68°C in a roller oven. Eventually, labeled probe were denatured at 95°C for 3 min, and placed immediately and completely into ice/water. Denatured probe were added to the prehybridized membranes. Hybridization was then carried out in a roller oven at 68°C for 18 to 20 h. Membranes were rinsed with 2X SSC/ 0.1% SDS and washed once in 2X SSC/ 0.1% SDS solution at 65°C for 15 min followed by two washes with 0.2X SSC/ 0.1% SDS at 65°C for 15 min. Similarly as for reference hybridization, membranes were placed onto 2 sheets of Whatman 3MM soaked with 2X SSC (with DNA side up, i.e. facing towards the imaging plate), wrapped into plastic film to prevent drying, exposed to imaging plate for 20 to 48 h and scanned using the Fuji FLA 3000 image reader at resolution of 50  $\mu$ m. After data acquisition, membranes were stripped using Strip-EZ<sup>®</sup> DNA kit (Ambion, USA) according to manufacturer's protocol and stored dry at 4°C. The success of the stripping was always checked using a hand-held monitor and by exposing the membranes in the same way as after the complex hybridization. If stripping is efficient, membranes can be re-used several times.

#### **2.2.8.5 Microarray buffers**

##### Lysis buffer with LiDS

100 mM Tris  
500 mM LiCl  
10 mM Na<sub>2</sub>EDTA  
1 % LiDS  
adjust to pH 8.0 with HCl, autoclave  
before use add DTT to 5 mM

##### Washing buffer with LiDS (RNase free)

10 mM Tris  
150 mM LiCl

1 mM Na<sub>2</sub>EDTA

0.1% LiDS

adjust to pH 8.0 with HCl

Washing buffer without LiDS (RNase-free)

10 mM Tris

150 mM LiCl

1 mM Na<sub>2</sub>EDTA

adjust to pH 8.0 with HCl (you may use Tris-HCl pH 8.0)

5X RT buffer self-made (RNase-free)

250 mM Tris

250 mM KCl

50 mM MgCl<sub>2</sub>

adjust to pH 8.0 with HCl (you may use Tris-HCl pH 8.3)

Prehybridization buffer

5X SSC

5X Denhardts

0.5% SDS

100 µg/mL Sheared salmon sperm/ herring sperm DNA (Promega, Germany)

ddH<sub>2</sub>O to final volume

ssDNA was heated at 95°C for 5 min prior to be added to the rest of the mixture which was pre-warmed to 65°C.

100X Denhardts:

10 g Ficoll

10 g Polyvinylpyrrolidone (PVP-360; MW: 360.000)

10 g BSA (Fraction V, Sigma)

Add ddH<sub>2</sub>O to 500 mL

Filter sterilize (0.2 µm) to remove particles and store at -20°C.

### 2.2.8.6 Data evaluation and analysis

The spot detection and quantification of hybridization signals from the phosphorimager data were analyzed using the Array Vision 8.1 software (Inter Focus, Mering, Germany) yielding the raw data of each experiment. Raw data from individual hybridizations were processed and normalized using the Haruspex expression database (<http://euklid.mpimp-goelm.mpg.de/gxdb/>). The local background signal of each 4 x 4 subgrid was subtracted from all related spot intensities. If the signal intensity of the spot was lower than 2 folds of local background (LB), it was replaced by local background value. These values were labeled later as “negative” gene activity values. Furthermore, the LB value was subtracted from all signal values which were more than 2 folds the LB value. For normalization, the signal intensities were divided by the mean of the all signal values on the array. The same initial procedures were used for the T7 reference and complex (cDNA) hybridization signals. The ratio of normalized complex value/normalized reference value was calculated thereby taking the amount of DNA spotted into account (as referred from the reference hybridization). As there were two replicates on each array, the average values of these technical replicates were taken as the gene activity.

To compare *pip2* mutants vs. wild-type, the ratio of the corresponding gene activities was obtained by dividing gene activity of mutant sample by the value of wild-type sample. Fold change was calculated by averaging expression ratios for mutant vs. control experiments from two biologically independent experiments. In order to allow division indicating a transcriptional ratio individual hybridization signals that were labeled ‘negative’ (i.e. not above 2 folds of the local background) were used as positive. Hence, if the gene activity of either the mutant sample or the wild-type sample was “negative”, the ratio was included as a positive value. Thus, these values were considered as estimates for the real induction or repression, since one of the values was indicated as below detection limit. However, ratios were labeled n.d. (not detected), if both gene activities of mutant and wild-type samples were labeled “negative” in both biological replicates. If transcription was only detected in one replicate, a mean value was calculated using ratio 1.0 (no change) for the “not detected” replicate, unless the resulting mean value would indicate a larger (lower) than two-fold change. In the latter case, values were not taken into consideration and labeled ‘o.o.’ (only once). Any results, which showed inconsistent, up- and down-regulated changes in replica experiments, were labeled ‘exp’ (conflicting experimental results). For further discussions about transcriptional changes of individual genes, only expression ratios smaller than 0.5 or larger than 2.0 were considered.

## 2.2.9 Genome-wide microarray analyses using Affymetrix ATH1 GeneChip

### 2.2.9.1 RNA preparation and Affymetrix GeneChip hybridization

Roots and leaves of 21-day-old hydroponically grown plants were used for whole genome microarray experiments. For each genotypes (wild-type and *pip2* mutants) three independent biological replicates were grown and harvested in parallel and stored at -80°C prior to RNA isolation. To decrease biological variation each replicate represented about ten plants.

Total RNA was isolated from 100 mg frozen material using RNeasy plant mini kit according to the manufacturer's protocol (Qiagen, Hilden, Germany). Five µg of RNA of *pip2* mutants and wild-type were then processed according to standard Affymetrix protocol and hybridized to Affymetrix GeneChip *Arabidopsis* ATH1 Genome arrays. Two rounds of hybridizations were done and, each in a different array facility. In fact, biological triplicates of *pip2;1* (s1), *pip2;2* (s2), *pip2;4* (s3) and *pip2;1-pip2;4* (s4) together with their wild type (wt1) were grown, harvested and hybridized in parallel whereas the second round of hybridizations was done using *pip2;2L-pip2;1sm* and wild type (WT) roots and leaves material extracting from plants grown in parallel but at different time than the previous mutants and wild-type. The first round of microarray hybridizations was carried out at the Affymetrix core lab facilities (Munich, Germany) using the Affymetrix One-Cycle Labeling and control (Target) kit according to the manufacturer's instructions. Concerning *pip2;2L-pip2;1sm* double mutants, RNA from roots and leaves tissues were processed and hybridized at the KFP Center of Excellence for Fluorescence Bioanalysis (Regensburg, Germany). RNA quality was controlled using Agilent bioanalyzer.

### 2.2.9.2 Normalization, statistical processing and data analysis

Due to annotation updates, Affymetrix probe sets were remapped onto actual *Arabidopsis thaliana* annotation and ambiguous probe sets aligning to more than one gene and probes without perfect matches were excluded from the analysis as previously described (Haberer et al., 2006).

CEL files were used for data processing. All probe set summary data were transformed to log-scale (basis 2). Chips raw data were normalized by Loess normalization (LMPN method) based on the local polynomial regression fitting method loess (Cleveland et al., 1992) operating on MA scale (Dudoit et al., 2000). Such polynomial regression method was required since datasets consisted of experiments from various Affymetrix lab facilities. Ignoring this would introduce additional, technical rather than biological bias. Consequently, a wild-type reference data set was generated by averaging and normalizing the expression of

each gene over all 6 wild-type hybridizations leading to more robust estimates of the real expression level. It was first checked whether ATH1 gene chip hybridization of the wild type from these two rounds yielded comparable results. Figure 7 shows that expression signals of the 3 replicates from wild-type of the first and second round were highly correlated. Consequently, this wild-type reference data set produced from the 6 WT replicates was used to calculate fold change ratio between mutants versus wild-type. Nonetheless, multiple testing hypotheses to check for significant differential expression were done for each mutant using his corresponding wild type replicates (See below).

An expression threshold of 6 (log basis 2) was chosen and genes showing expression below this threshold were excluded from further calculations. Similarly, a 0.5/ -0.5 (log basis 2) fold-change mutants versus wild-type cutoff was applied.

**Figure 7. Scatter plot of hybridizations of the different wild type biological replicates obtained from two different Affymetrix laboratory facilities.**

Wt1.1, wt1.2 and wt1.3 are the 3 biological replicates for the first facility plotted against each other and against the 3 biological replicates of A\_242D\_W.WT 1 to 3, which correspond to the wt obtained at the second Affymetrix facility.

After this filtering, the statistical significance for differential gene expression between mutants and wild-type reference was computed by multiple hypothesis testing (Baldi & Long Bayesian regularized t-test, Welch 2-variance t-test) and correction for multiple testing was done using Benjamini-Hochberg FDR (False Discovery Rate)-controlling method (significance level 0.05) (Benjamini and Hochberg, 1995). The top hundred genes passing all these requirements were used for further analyses and assigned to functional categories using MapMan software version 2.0 (Thimm et al., 2004) (see also Method 2.2.10).

### 2.2.10 Co-expression analyses

To identify genes that exhibit co-regulation with *PIP2* genes, the *Arabidopsis* Co-expression Data Mining Tool (ACT) (Manfield et al., 2006) and the Bio-Array Resource (BAR; Expression Angler tool) (Toufighi et al., 2005) were used. These programs calculate the correlation coefficients for all genes as compared to the query gene. Both web-based tools use publicly available ATH1 Affymetrix Whole Genome GeneChip expression data. The datasets used by ACT come from NASCarrays (322 ATH1 samples) while BAR uses 392 ATH1 samples from NASCarrays as well as data sets from the AtGenExpress Consortium (Tissue, Abiotic Stress, Pathogen or Hormone series) and from the BAR itself. In this study, *PIP2* co-expression analyses were done using a Pearson correlation coefficient cutoff of 0.6. Both the positively ( $r\text{-value} \geq 0.6$ ) and negatively ( $r\text{-value} \leq -0.6$ ) co-expressed genes were retrieved from ACT using all available ATH1 array experiment and from BAR using AtGenExpress Abiotic Stress, Pathogen or Hormone datasets (all experiments involving seeds were excluded from the analysis). Moreover, in the case of AtGenExpress Abiotic Stress subset of arrays, co-expression analyses were done for roots and aerial parts separately. In each case, a list was created containing the co-expressed genes and the correlation coefficient. Co-expressed genes were then assigned to functional categories using MapMan software version 2.0 (Thimm et al., 2004). MapMan categories were slightly modified for those that cover few genes. Merging of categories was done as previously described by Lisso et al. (2005). Statistical analyses were done to determine the significance of over-representation for each category. The probability for the observed frequency of genes assigned to a category with respect to the expected frequency of the category in the whole genome (based on MapMan) was calculated using a two-sided Fisher's exact test.

### 2.2.11 Principal component analysis (PCA) of *PIP* transcriptional responses to diverse stimuli using publicly available microarray data

Public efforts have been directed to *Arabidopsis* global transcript profiling that monitored the response of the plant under different treatments. Large sets of data have been made publicly available through several databases, e.g. TAIR, NASC, and many web-based tools (e.g. Genevestigator, BAR, ACT) have been developed to assist the interpretation of these large microarray gene expression databases. The Genevestigator Meta-Analyzer tool was used to extract *PIP* transcriptional responses in a broad range of stress conditions to investigate whether *PIP2* genes can be distinguished based on their differential stress responsiveness. Especially useful has been the AtGenExpress consortium which had generated standard Affymetrix microarray data for *Arabidopsis*. Although, data from NASC, TAIR, and several other sources are made available at Genevestigator, only AtGenExpress data were used. In contrast with other sources, the AtGenExpress consortium provided more homogenous and more comparable data since all experiments were done in a similar way and using *Arabidopsis thaliana* Col-0 ecotype. In addition, in many cases, roots and leaves were analyzed separately. Here, the abiotic, biotic and hormone treatment subsets of array generated by the consortium were used. A total of 61 different arrays were exploited. Expression ratios of *PIP* genes with respect to control experiments were extracted for the 61 arrays using the Genevestigator Meta-Analyzer tool (Version 3). In order to avoid any bias, several atypical treatments were removed (i.e. genotoxic stress (abiotic stress), cycloheximide, MG13 and PNO8 treatments (chemical treatments)). Finally, expression ratios of *PIP* genes in 54 conditions were retained (Supplementary table 9 for *PIP* genes expression ratio and list of all stress conditions and treatments). After expression ratios were log-transformed to the basis 2 and raw-centered, data were subjected to a principal component analyses (PCA) to explore the concomitant or differential participation of *PIP* genes to diverse stimuli. PCA reduces the dimensionality of the multivariate data while only slightly reducing information: a large proportion of the variance will be explained by a smaller number of variables. Stress or treatments with great variances contribute more significantly to the differentiation of *PIP* transcriptional responses. The angular distance was used to extract from the PCA a subset of stimuli that contributed most significantly to the differentiation or association. The radius was arbitrarily set to  $r > 3$  resulting in a selection of 8 out of 54 conditions.

### 2.2.12 Microscopy

Stereomicroscopy, light and fluorescence microscopy were used to visualize and photograph *Arabidopsis pip2* mutants, *PIP2* promoter::GUS transgenic plants as well as wild-type plants. For this purpose, a Leica MZ16F microscope with Leica DFC 320 camera was used and light and fluorescence microscopy were carried out with a Zeiss Axioskop.

GFP, Propidium iodide (PI, sigma, P-4170), FM<sup>®</sup>4-64 (*N*-(3-triethylammoniumpropyl)-4-(6-(4-(diethylamino)-phenyl)hexatrienyl)pyridinium dibromide (Molecular Probes, Germany) and DAPI fluorescence were visualized using Confocal Laser Scanning microscope (LSM 510 Axiovert 100 M; Carl Zeiss, Jena).

For staining, 1 week-old seedlings grown on vertically orientated plates were immersed in 0.1 mg/mL PI (in water) for 30 min, washed three times with double-distilled water and observed thereafter.

Regarding FM4-64, seedlings were incubated in a 10  $\mu$ M FM4-64 solution for 10 min, briefly rinsed with water and immediately observed. Observation should be quick since FM4-64 dye is internalized.

The LSM 510 was equipped with an argon laser emitting at 488 nm and helium-neon lasers emitting at 514, 543 and 633 nm, among others. GFP was excited with Argon laser at 488 nm and detected with a 505-530 bandpass; Others fluorescence were detected with the following wavelength for excitation and detection: 543 nm (or 488 nm) and 578-642 (565-615) bandpass for Propidium Iodide, 514 nm and 620-670 nm for FM4-64, and 364 / 454 nm and 488 nm for DAPI. C-Apochromat 10x/0.45, Plan-Neofluar 10 $\times$ /0.3, C-Apochromat 20x/0.45w or Plan-Neofluar 20 $\times$ /0.5Ph2 water immersion objectives were used for both observation and image recording. Systematically, monochrome images were taken sequentially at each wavelength. Artificial colors were assigned to the images taken for each excitation wavelength: green for 488 nm, red for 543 nm, and blue for 633 nm. Images were further processed using the AIM software, version 3.0 (Carl Zeiss, Jena).

### 3 RESULTS

#### 3.1 *PIP2* expression in *Arabidopsis* plants

##### 3.1.1 Analysis of *PIP2* promoter::GUS expression profiles in *Arabidopsis* plants

Plants are sessile organisms and have therefore to adapt to their challenging environment. Many processes in plant development are dependent on massive water flow into and out of the cells such as water uptake by roots, elongation growth, phloem transport or even photosynthesis. These necessary water movements into and within the cells/tissues and the fine regulation required for plant growth may suggest a putative involvement of aquaporins. Identifying the cellular expression pattern constitutes a major piece of information in elucidating the function of a gene. Thus, functional analysis of *PIP2* genes function requires a precise knowledge of the specific expression profile of these genes. To gain a comprehensive insight into the *Arabidopsis PIP2* expression patterns *in planta*, the histochemical localization of the bacterial  $\beta$ -glucuronidase gene (*uidA* or *gusA*) commonly referred to as GUS was investigated in transgenic plants expressing this reporter gene under the control of different *PIP2* promoters.

DNA fragments corresponding to about 2.5 kb 5' upstream regions including the start codon of the *PIP2* genes were fused to the GUS sequence within the T-DNA of the destination vector pBGWFS7 (Fig. 5b). The resulting construct was then transferred into *Arabidopsis thaliana* plants (Methods 2.2.2.4 and 2.2.4.6). GUS expression was confirmed on T1 transgenic plants (self-fertilization of the primary transformants) and more precise analyses were done on T2 and T3 generations. Different growth stages and organs were analyzed on 3 to 5 lines for each *PIP2* promoter::GUS constructs. All lines of a particular *PIP2* promoter::GUS fusion showed about the same expression profile although the expression level varied depending upon the lines. Similarly, *Arabidopsis thaliana* transformant plants ecotype Col-0 or C24 exhibited similar expression pattern except for *PIP2;7* where slight differences could be observed between the two different ecotypes as explained below.

##### **Differential expression profile of *PIP2* promoter::GUS fusions in *Arabidopsis***

Most *PIP2* genes exhibited a wide-spread expression in roots, leaves and flowers, but their expression pattern was different (Fig. 8). *PIP2;1*, *PIP2;2* and *PIP2;7* exhibited high GUS activity in roots as well as in leaves, while *PIP2;3* and *PIP2;5* showed a relatively lower GUS activity in both organs. In contrast, *PIP2;4* was strictly root-specific and strongly expressed in lateral roots and younger roots but not in hypocotyl, while *PIP2;6* was predominantly detected in young leaves and the main root. *PIP2;8* exhibited a special pattern in roots and

leaves; significant expression was observed in the basal part of young leaves and at the base of emerging lateral roots (Fig. 8 and 9).

**Figure 8. Histochemical localization of PIP2::GUS activity in vegetative tissues.**

Distinct tissues of 8 to 13 day-old seedlings grown *in vitro* were analyzed and photographed. For expression in leaves, plants were grown in soil. (a, f, k, p, u, z, ae, aj) Eight to Thirteen-day-old seedlings; arrows point to hypocotyl; (b, g, l, q, v, aa, af, ak) section of the root hair zone of 2-week-old seedlings; arrows designate endodermis (c, h, m, r, w, ab, ag, al) root tip of 2-week-old seedlings; (d, i, n, s, x, ac, ah, am) leaves of 3 week-old plants grown in soil; (e, j, o, t, y, ad, ai, an) flowers of 5- to 6-week-old plants grown in soil.

Nevertheless, all *PIP2* members exhibited GUS activity in the root hair zone important for nutrient and water uptake. Except for *PIP2;5* and *PIP2;6* all members were expressed in the root hairs as well (Fig. 8 and 9). By and large, these expression patterns of *PIP2* genes were corroborated by AtGenExpress array expression analyses in different anatomical structures (Fig. 10, see below).

The cellular expression in roots revealed additional differential patterns. *PIP2;3* and *PIP2;8* were strictly confined to cells within the vascular tissue clearly excluding the endodermis (Fig. 8). Instead, *PIP2;1*, *PIP2;2*, and *PIP2;7* were found to be highly expressed in several tissue layers in the stele and adjacent endodermis. In the elongation and maturation zone *PIP2;7* exhibited stronger and wider cellular expression throughout the root (Fig. 8ag; see below). *PIP2;5* had a rather similar pattern with expression in stele and in endodermis. In case of *PIP2;2*, expression was also extended into the cortex layer (Fig. 8). *PIP2;4* and *PIP2;6* were the only members which were not highly expressed within the stele tissue. *PIP2;4* was also found in outer cell layers, in particular in the cortex in contrast to array expression data. *PIP2;6* was mostly confined to endodermis (Fig. 8 and 10).

Differential expression was also detected in root tip. *PIP2;1*, *PIP2;2* and *PIP2;3* showed predominant GUS activity in the meristematic region (Fig. 8). *PIP2;4* and *PIP2;5* were not transcribed in this region; however, *PIP2;5* interestingly showed a particularly strong expression in emerging lateral roots (Fig. 9). Surprisingly, *PIP2;6* was confined to the quiescent center (Fig. 8ab). Although the highly homologous *PIP2;7* and *PIP2;8* clearly showed differential expression in all other parts, within the root tip region both were found in the emerging vascular bundle (Fig. 8).

In leaves, *PIP2;1*, *PIP2;2*, *PIP2;3*, *PIP2;5*, *PIP2;6* and *PIP2;7* were expressed in vascular tissues as well (Fig. 8). *PIP2;1*, *PIP2;2*, *PIP2;5*, *PIP2;7*, and in young leaves *PIP2;6* exhibited a broader pattern with expression also observed in mesophyll. Interestingly, significant GUS activity in stomata was only detected for *PIP2;3* (Fig. 9). Although microarray technique has been able to show expression of *PIP2;1* in guard cells (Leonhardt et al., 2004), we did not observe it with GUS histochemical assay. Similarly, using microarray, Leonhardt *et al.* (2004) detected expression of *PIP2;1*, *PIP2;2*, *PIP2;6* and *PIP2;7* in mesophyll cells.

**Figure 9. GUS expression in different cell types.**

(a to f) Expression in root hairs of 2-week-old seedlings expressing *PIP2* promoter::GUS constructs: (a) *PIP2;1*, (b) *PIP2;2*, (c) *PIP2;3* promoter::GUS; (d) *PIP2;4*, (e) *PIP2;7*, and (f) *PIP2;8*. No expression could be detected for *PIP2;5* and *PIP2;6* promoter::GUS lines. (g) GUS Expression in young lateral root of 2-week-old seedling expressing a *PIP2;5* promoter::GUS construct. (h) Emerging lateral roots of 2-week-old plant expressing *PIP2;8*::GUS. (i) Leaf surface of 2-week-old transgenic seedling expressing a *PIP2;3* promoter::GUS construct. Stained stomata are indicated by arrows. The insert shows a magnification of a single stoma.

All *PIP2* genes were expressed in flowers and siliques, yet again in a differential manner with overlapping, but unique patterns (Fig. 8 and Supplementary Figure 1). Only *PIP2;1*, *PIP2;2*, *PIP2;3* or *PIP2;5* as well as *PIP2;6* were expressed in sepals and in petals similar to their expression in true leaves, whereas these genes and all other *PIP2* members were found in different parts of the reproductive organs (Fig. 8). In the filaments, *PIP2;1* and *PIP2;7* were strongly expressed, whereas *PIP2;2* and *PIP2;3* showed a weaker staining and *PIP2;6* was confined to their upper region. Only *PIP2;1* and *PIP2;4* were found in anthers, with *PIP2;4* being specifically confined to anthers in young unopened flowers. In the female part *PIP2;8* was specifically expressed in the upper part of the ovary just below the style similar to *PIP2;6*. Finally, *PIP2* gene expression in the stigma and style was only found for *PIP2;2*, while *PIP2;5*, was also expressed in the stigma and *PIP2;1* confined to the style. In

*Arabidopsis* ecotype Landsberg erecta, analysis of the stigma transcriptome also revealed expression of *PIP2;2* in the stigma but not of other isoforms (Swanson et al., 2005).

During flowering stage, *PIP2;5* was the only *PIP2* member active in the abscission zone, while several *PIP2* genes were located to that region in siliques (Fig. 8 and Supplementary Figure 1).

### 3.1.2 *PIP* gene expression profile based on microarray data

Transcripts expression profiling using microarray technology has become a powerful tool in biology and such studies contain a wealth of information that has been made available in public databases. Informations concerning one or more genes in multiple experiments can be queried using such tools. Thus, besides GUS histochemical assay, the Genevestigator Meta-Analyzer tool (Version 3; Zimmermann et al., 2005) was used to retrieve the gene expression profile of *PIP2* as well as *PIP1* genes in various tissues and organs in order to get insight into expression of the whole *PIP* family in *Arabidopsis*. Such analyses could give valuable information on the overlapping or differential expression profile between *PIP2* and *PIP1* members. Transcript profile of 40 anatomical structures (organ, tissue) was obtained and hierarchically clustered using the Genevestigator Meta-Analyzer tool (Fig. 10). Data were clustered by gene and profile using Pearson correlation. Unfortunately, one inconvenient of the data produced by commercial array Affymetrix whole genome ATH1 GeneChip is that it harbors several unspecific probesets that hybridize more than one gene. Thus, *PIP2;2* and *PIP2;3* as well as *PIP2;7* and *PIP2;8* hybridize the same probeset, respectively. Consequently, these genes can not be discriminated by the Affymetrix ATH1 array.

Regarding *PIP2* genes, the data retrieved from Genevestigator were in accordance with those obtained with *PIP2* promoter::GUS transgenic plants (see above). In case of *PIP1* genes, *PIP1;1*, *PIP1;2* and *PIP1;3* clustered together and showed nearly identical expression pattern and wide-spread organ expression (Fig. 10). *PIP1;4* exhibited a slight difference by showing higher expression in aerial parts than in roots but, yet, showed expression in all organs. *PIP1;5* was the only *PIP1* member not detected in root endodermis and cortex. Interestingly, *PIP1;1*, *PIP1;2* and *PIP1;3* showed an extremely similar expression with *PIP2;1*, *PIP2;2/2;3* and *PIP2;7/2;8* (Fig. 10).

Thus, differential expression pattern of *PIP2* members argue in favor of a different function of *PIP2* genes with implications in all plant tissues for some *PIP2*, e.g. *PIP2;1*, *PIP2;2* and *PIP2;7* that are co-expressed with *PIP1*.

**Figure 10. Hierarchical clustering of the 13 *Arabidopsis* PIP isoforms (Genevestigator, May 2007).**

Expression of PIP2 in 40 anatomical structures. Data from about 3000 Affymetrix ATH1 GeneChip were retrieved using the Genevestigator Meta-Analyzer tool and then clustered by genes and profiles. A Pearson correlation was used for clustering.

### 3.1.3 PIP2;4 cellular and subcellular localization

The differential expression pattern observed for *PIP2;4* compared to other *PIP2* members using GUS histochemical assay prompted me to do more pronounced analyses. Thus, its cellular expression pattern was re-examined using transgenic plants expressing a *PIP2;4* promoter::*PIP2;4*-ORF-GFP fusion protein. Moreover, these transgenic plants did not only allow to visualize the cellular expression patterns, but also to investigate more precisely the subcellular localization of the PIP2;4-GFP fusion protein.

Transgenic plants expressing a *PIP2;1* promoter::*PIP2;1*-ORF-GFP fusion protein were also generated and use for comparison with PIP2;4 cellular pattern. Observations of roots from these *Arabidopsis* seedlings by Confocal Laser Scanning Microscopy showed GFP activity confined to the outer parts of the roots for PIP2;4 (Fig. 11b and d). Expression seemed to be localized to cortex and exodermis, while it was predominantly detected in vascular tissue in case of PIP2;1 (Fig. 11a and c). The visualization of GFP activity in these transgenic plants confirmed data observed using GUS histochemical assay (See above, Fig. 8).

**Figure 11. Cellular localization of PIP2 fused to GFP in *Arabidopsis* root seedlings.**

The figures show laser-scanning confocal microscopy of GFP fluorescence emitted by root cells of 1 week old transgenic *Arabidopsis* seedlings grown in agar plate. All Panels are Z-stack confocal images (about 120 μm at 4 or 5 μm interval). In bottom panels, root cell walls were stained with propidium iodide for 30 min, washed and observed. Plants expressed the following fusion proteins: PIP2;1 Promoter::*PIP2;1*-ORF-GFP (a and c), PIP2;4 promoter::*PIP2;4*-ORF-GFP (b and d). Scale bar, 50 μm.

PIP2 proteins are assumed to be water channel localized to the plasma membrane and this plasma membrane location has been experimentally shown by immunocloning and biochemical analyses for PIP2;1, PIP2;2 and PIP2;3 (Daniels et al., 1994; Kammerloher et al., 1994) or using GFP fusion proteins for PIP2;1 and PIP2;7 (Cutler et al., 2000; Boursiac et al., 2005). The plasma membrane location of other PIP2 proteins, PIP2;5 being the only member for which no experimental evidence for plasma membrane localization is available, has been made highly likely based on protein identification using mass spectrometry (Elortza et al., 2003; Alexandersson et al., 2004; Nelson et al., 2006). However, it is impossible to completely exclude contaminants by endomembranes from such analyses. Moreover, evidence is increasing that suggests a location in more than one membrane and compartment, and, also, that MIPs may move depending on physiological states or environmental disturbances (Barkla et al., 1999; Vera-Estrella et al., 2004; Boursiac et al., 2005). Hence, precise analyses using a PIP2;4::PIP2;4-ORF-GFP fusion protein were carried out to check whether or not PIP2;4 was localized at the plasma membrane and/or other membranes. The PIP2;4 plasma membrane localization was confirmed using multiple fluorescence labeling observed by confocal microscopy (Fig. 12a to f).

**Figure 12. Plasma membrane localization of PIP2;4.**

The figures show laser-scanning confocal micrographs of the fluorescence emitted by root cells of transgenic plants. Panels A to C are Z-stack confocal images (60  $\mu\text{m}$  at 5  $\mu\text{m}$  interval). (a and d) GFP fluorescence; (b) FM4-64 fluorescence; (c) merged image of a and b showing co-localization of PIP2;4::PIP2;4-ORF-GFP fusion protein with the vital dye FM4-64. (e) DAPI staining of nucleus; (f) merged image of d and e. Scale bar, 20  $\mu\text{m}$ .

The GFP signal was easily observed at the plasma membrane of root cells and in particular

root hairs (Fig. 12a and d). The plasma membrane localization of PIP<sub>2</sub>;4 in *Arabidopsis* root cells was first demonstrated by the co-localization with the vital dye FM4-64, which stains specifically the plasma membrane phospholipids under the conditions used (Fig. 12a to c). Additionally, the labeling of the nucleus using DAPI clearly eliminated the vacuolar localization of PIP<sub>2</sub>;4, since no membrane invagination around the nucleus could be observed (Fig. 12d to f).

### 3.2 Isolation and molecular characterization of *pip2* insertional mutants

Reverse genetics and the use of loss-of-function mutants provide a reliable approach to explore the integrated function of a gene. Here, to investigate the function of individual PIP2 aquaporins in *Arabidopsis thaliana*, a collection of T-DNA or transposon insertion mutants was established (see Materials 2.1.1, Table 1).

#### 3.2.1 Isolation of *pip2* single and double mutants

The *pip2* insertion mutant candidates were isolated by screening publicly accessible seed collections and characterized by PCR genotyping (Fig. 13; Method 2.2.5). Whenever possible, several independent T-DNA or transposon insertion lines were screened for each *PIP2* gene in order to obtain at least two independent alleles. Insertions lines were first tested for the presence of T-DNA or transposon and lines with insertion in both alleles (homozygous plants) were obtained. Insertions were first confirmed by PCR using reverse (or forward) *PIP2* gene specific primer in combination with primer specific for the T-DNA left border. Homozygous plants were then revealed by PCR amplification of the *PIP2* coding sequence with reverse and forward gene-specific primers. DNA from homozygous plants gave no amplification product whereas DNA from heterozygous and wild-type plants did. All the PCR for screening of *PIP2* insertion mutants provided data essentially identical to those shown in Figure 13.

PIP2 are highly homologous in their amino-acid sequence and single knockout mutants may be compensated by other genes in case PIP2 members would share functional redundancies. Multiple mutants where two or more genes are mutated may help identifying functional redundancy or even interacting partners in biological pathways. Thus, double mutants were created by crossing single *pip2* mutants (Method 2.2.1.2). Progeny of F1 heterozygous plants were then screened for homozygosity of the insertions by PCR genotyping identical to the single mutants. The theoretical segregation was 1:15 among the F2 population, as long as there was no chromosomal linkage of the loci (Fig. 13c and d).

By sequencing the respective PCR products obtained with T-DNA and gene-specific primer combinations, the position of the insertion sites within the corresponding *PIP2* genomic sequence were established. The position of the insertions for each mutant is depicted in Figure 17.

**Figure 13. Screening of *pip2* T-DNA insertion mutants.**

*pip2* single and multiple mutants were characterized by PCR genotyping. (a) and (b) Ten *Arabidopsis* plants of a *PIP2;4-1* transposon insertion were screen to obtain homozygous mutants. T-DNA insertion was confirmed by PCR using reverse primer specific for *PIP2;4* and primer specific for the T-DNA left border (amplification using T-DNA primer and forward primer specific for *PIP2;4* did not give product in this mutant and is therefore not shown for better clarity). (b) PCR amplification of the *PIP2;4* coding sequence with *PIP2;4* reverse and forward gene-specific primers to reveal homozygous plants. (c) to (f) show PCR genotyping for a *pip2;2-3/pip2;1-1* double mutant. F2 *Arabidopsis* plantlets were screened to obtain homozygous mutants. Confirmation of T-DNA insert by PCR using the required T-DNA left border primer and (c) *PIP2;1* or (d) *PIP2;2* gene specific primers. (e) and (f) show PCR amplification using reverse and forward gene specific primers of the *PIP2;1* and *PIP2;2* coding sequence, respectively. Red circles indicate homozygous T-DNA insertion mutant plants.

### 3.2.2 Molecular characterization of *pip2* insertional mutants

Since T-DNA or transposon insertion does not necessarily lead to loss of transcripts, the absence of the respective mRNA transcripts in the insertion lines had to be confirmed. Thus, *PIP2* mRNA expression in the mutant lines was tested by RT-PCR using gene specific primers for amplification of the gene (Fig. 14; Method 2.2.4.2). The gene specific-primer combinations were designed in regions flanking introns to generate PCR products from cDNA that were distinctly smaller than the products amplified from genomic DNA using the same primer combinations. Most insertion lines resulted in loss of transcripts and, hence, generated knockout mutants (Fig. 14; see Table 1 for a complete list of *pip2* mutants). In case of *PIP2;4* and *PIP2;8* only one knockout mutant could be isolated.

**Figure 14. Agarose gel separation of PCR products amplified from cDNA of wild-type and *pip2* mutant lines.**

RNA extracted from wild-type and *pip2* mutants was extracted and used to synthesized cDNA. The expression of Tubulin9 is shown as a control (a). As expected, product amplified from genomic DNA (gDNA) was bigger than products polymerized using cDNA indicating that was no contamination with gDNA. Expression of the respective *PIP2* genes was then analyzed in *pip2* mutants and confirmed loss of transcripts in (b) *pip2;1*, *pip2;2*, *pip2;4* single and double mutants, (c) *pip2;3* mutants, (d) *pip2;5* mutants, (e) *pip2;6* mutants and (f) *pip2;8* mutant.

Since T-DNA insertions in the genome can result in local DNA rearrangement or loss of DNA, the integrity of the neighboring genome was confirmed by PCR using primer combination specific for that region. Thus, flanking genomic sequences were obtained using approximately 1.5 kb genomic fragments amplified by PCR, digested with restriction enzymes and characterized by their predicted size and characteristic restriction pattern. These analyses confirmed that for all mutants no aberrations of the directly flanking genomic region had occurred.

Eventually, since mutants have not been back-crossed into wild-type, a more careful examination of their insertion site and potential additional insertions was required, because independent insertions could also influence putative phenotypes. Therefore, Southern blot analyses were performed on *pip2* knockout mutants to analyze the structure of the T-DNA insertion lines. Genomic DNA from *pip2* mutant was digested with a restriction enzyme, blotted and hybridized with a probe generated by polymerization of a region of the T-DNA left border nearby the insertion sites (Fig. 15). Any T-DNA insertion would hybridize the

probe and generate a fragment visible on the blot (Fig. 15 and 16). Two or three different restriction enzymes had been selected. Using such strategy, it was therefore possible to identify whether *pip2* mutants exhibited additional T-DNA within their genome.

**Figure 15. Southern blot strategy for analyzing T-DNA insertion in *pip2* mutant genomes.**

Genomic DNA from *pip2* mutant plants is digested with restriction enzyme (R1), run on an agarose gel, and transferred to nylon membrane (Methods 2.2.4.8). The blot is hybridized with a T-DNA probe produced from PCR amplification of the T-DNA left border. Any digested T-DNA will produce a fragment that would hybridize with the radiolabeled probe and will be further visualized on the blot. LB: T-DNA left border; RB: T-DNA right border.

These analyses showed a single T-DNA insertion for both SM lines (*pip2;1-2* and *pip2;4-1*; Fig. 16 and Table 5) as well as both *pip2;2* mutant lines (*pip2;2-3* and *pip2;2-4*; Fig. 16 and Table 5). In the other single mutants, additional bands were found. They may mean insertions at independent loci or more complex T-DNA insertions at the *PIP2* loci. The latter has been already indicated by the fact that the inserts harbor two T-DNA left borders (see also Fig. 17). However, for these mutants, except for *pip2;8*, at least two independent mutant alleles were obtained. Therefore any phenotype observed in both lines, could consistently be attributed to the mutation at the corresponding *PIP2* locus. The *pip2;1-1* mutants has been previously characterized and several additional T-DNA insertions were observed (Affenzeller, 2003). Two double mutants were also checked and showed exactly the same profile as their corresponding single mutants (Fig. 16).

**Figure 16. DNA blots of *pip2* knockout mutants.**

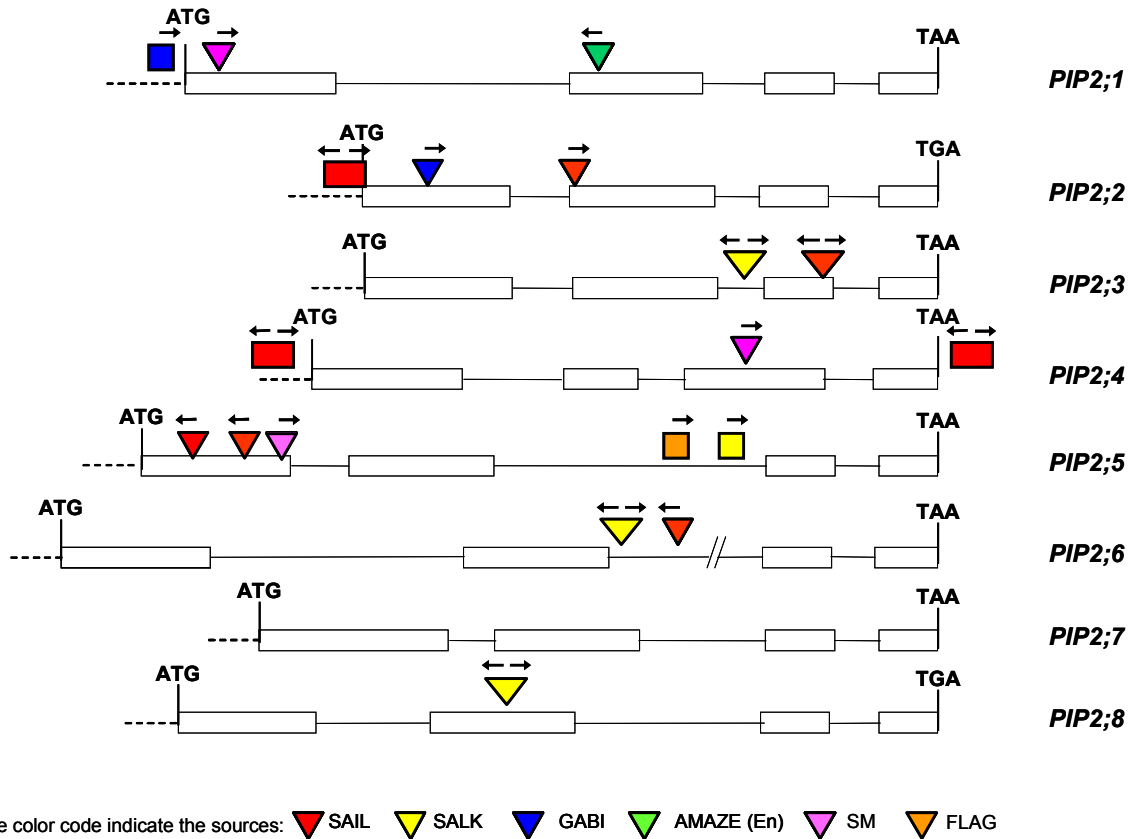

Genomic DNA (2 µg) was digested, separated and transferred onto a positively charged nylon membrane and further hybridized with a radioactively labeled probe. Specific probes were produced by PCR amplification of the T-DNA left border of various T-DNA lines (SM, Sail, Gabi and Salk lines). Each line represents a DNA digest for a particular *pip2* mutant and enzyme. The respective T-DNA probes used are listed on the top of the Figure (e.g. SM lines, Sail lines). BH: BamHI; Bg: BglIII; EV: EcoRV; H: Hind III; N: NcoI; M: DNA Marker.

**Table 5. T-DNA or transposon flanking restriction fragments of *pip2* mutants.**

Genomic DNA extracted from various *pip2* knockout mutants was extracted and submitted to restriction digest. Expected sizes for each digest are indicated. For several mutants (indicated by an asterisk), PCR genotyping revealed a T-DNA left border on both sides of the insertion, indicating a complex T-DNA insertion. Accordingly, two restriction fragments were expected.

Mutant	Insertion verified	Additional insertions	BamHI	BglIII	EcoRI	EcoRV	HindIII	NcoI	XhoI

Molecular characterization of *pip2* knockout mutants is a crucial step prior phenotypical characterization. Here, more than twenty *pip2* mutants were analyzed producing a valuable collection to study integrated function of *PIP2* genes. Figure 17 summarizes *pip2* single mutants characterized in this work (see also Table 1).

**Figure 17. Collection of *pip2* insertional mutants in *Arabidopsis thaliana*.**

Except a *PIP2;5*\_FLAG line which was in Ws ecotype, all *pip2* mutant were in the Columbia background. Position of the T-DNA insertions were verified by sequencing and arrows indicate orientation of T-DNA left border (two arrows indicate a left border on both sides of the insertion). Accordingly, the arrows indicate the En-1-element border for the transposon insertion in Amaze-(En) line or the nonautonomous defective *Spm* (*dSpm*) element in SM lines. Triangles represent knockout mutants, while squares indicate homozygous mutants in which transcripts were detected. Large boxes represent exons, while lines represent introns. Start (ATG) and stop codons (TAA/TGA) are indicated.

### 3.3 Phenotypical analysis of *pip2* knockout mutants

#### 3.3.1 Growth responses of *pip2* mutants in standard and water stress conditions

PIP2 members are thought to be involved in water transport in plants and, as a consequence, a role in water deficit tolerance has been suggested. Plant responses to water deficit depend on the severity, i.e. on the amount of water lost, the rate of loss and the duration of the stress. Water deficit results from various stresses such as low (freezing) temperature, drought and salt enrichment in soil. For instance, application of NaCl to the root system of plants affects plant growth and development by exerting a strong osmotic water stress by lowering the water potential of the surrounding substrate, but it also exerts a toxic effect of the ions involved. Thus, both water relations are strongly affected by NaCl and toxicity of ions may harm the plants. Both pathways could influence the expression of aquaporins. Responses to abrupt water deficit as in many experimental approaches may occur in short time within a few minutes for the biophysical alterations and within hours or days for long-term adaptations depending on cellular and whole-plant mechanisms (Bray, 1997; Munns, 2002; Xiong and Zhu, 2002).

In *Arabidopsis*, *PIP* genes stress responsiveness has been shown at the transcriptional level (Kreps et al., 2002; Seki et al., 2002a; Affenzeller, 2003; Jang et al., 2004; Alexandersson et al., 2005; Boursiac et al., 2005). *Arabidopsis* plants with modulated expression of several PIPs also suggested their role in water stress conditions but none of them could demonstrate direct involvement of a particular *PIP* gene (Martre et al., 2002; Aharon et al., 2003; Jang et al., 2007a).

In order to check whether any PIP2 member plays a role in water stress tolerance, possible growth or developmental alterations of *pip2* mutants with respect to the wild-type were investigated. Whole plant growth including the roots was observed on vertical gelrite 0.5X MS plates supplemented with different concentrations of NaCl or sorbitol to account for ionic and osmotic stresses (see Method 2.2.1.6). Except for *pip2;4* and *pip2;8*, where only one mutant was available, two independent homozygous insertion lines were analyzed for each of the *PIP2* genes. *PIP2;7* was not included at all, because a knock-out mutant was not available. Since PIP2 proteins are highly homologous, a single knockout mutant may be covered by other genes. Thus, the use of multiple mutants should provide evidence toward either differential functions or functional redundancies or even interacting functions of *pip2* isoforms. Two selected *pip2* double mutants were generated and tested in the same way as for the single mutants asking the question whether these combinations would lead to additional phenotypes. Those double mutants were selected based on their expression pattern, e.g.

*PIP2;1* and *PIP2;2* are highly expressed in all organs. The particular pattern observed for *PIP2;4* prompted us to generate double mutants including *PIP2;4* as well.

Germination was not affected in any of the mutants, if directly planted on standard medium or on plates with 50 mM NaCl, 100 mM NaCl or 200 mM sorbitol.

In order to impose water stress to young seedlings, four-day-old seedlings germinated on vertically orientated control plates were transferred to fresh 0.5X MS plates supplemented with either 50 mM NaCl, 100 mM NaCl or isoosmotic 200 mM sorbitol to impose water and/or ionic stress and onto control plates without additional solutes. Four-day-old seedlings did not show any growth phenotype before being transferred, with the exception of *pip2;5-1* seedlings that were slightly smaller in comparison to other wild-type control and other mutants (Fig. 18). However, this phenotype is likely not due to *PIP2;5* loss-of-function since a second individual mutant, *pip2;5-3*, did not show this growth reduction phenotype (Fig. 18).

**Figure 18. Four-day-old seedlings of wt and *pip2* mutant.**

The *pip2* mutants and corresponding wild-type were grown on plates in a vertical orientation and seedlings were photographed after 4 days.

After transfer, plants were further grown for seven days in a vertical position and root growth was recorded by marking them daily and measuring root elongation (Fig. 19). Root elongation and whole plant phenotype were assessed separately. In standard medium, *pip2* mutants did not show any growth alteration (Fig. 19 and 20). Although *pip2;5-1* mutant showed slightly, but significantly reduced growth (about 20%), this phenotype was not confirmed by the independent *pip2;5-3* mutant (see below and Fig. 19 and 20).

However, when growth of roots and whole plants was assessed under different water stress conditions on vertical agar plates, differential sensitivity of *pip2* mutants could be observed. In general, growth of wild-type plants on 50 mM NaCl led to a reduced root elongation of about 25%, while it was around 55% in case of 100 mM NaCl. Osmotic stress imposed by sorbitol showed a reduced root elongation comparable to that of 100 mM NaCl, since root growth was inhibited by about 45%. These different conditions allowed the analysis of *pip2* mutants growth under mild as well as severe water stress. As shown in Figure 19, root elongation of most *pip2* mutants exposed to various water stresses was not affected with respect to the wild-type.

**Figure 19. Relative root growth of *Arabidopsis* wild-type and *pip2* mutants under various water stresses.**

Plants were germinated and grown for 4 days on standard medium plates, further transferred to gelrite plates containing standard medium supplemented or not with increasing concentrations of NaCl or sorbitol. Growth measurements were conducted up to seven days after seedlings were transferred on fresh plates. Relative Root Growth (RRG) of *pip2* mutants was calculated with wild-type root length set to 100%. Bars represent Relative Root Growth (RRG; percentage) of *pip2* mutants with respect to the wild-type 7 days after transfer. Bars are means ( $\pm$  SE) of 3 to 5 independent experiment using 6 seedlings per genotype for each experiment. P-values were calculated using an unpaired Student's t-test assuming unequal variance to compare mean root length of wild-type and mutant plants. Asterisks indicate statistically significant differences ( $p < 0.05$ ).

Actually, the most severe phenotype was observed for the *pip2;5-1* mutant. Its root growth was significantly retarded on 50 mM NaCl and was almost stopped on 100 mM NaCl (Fig. 19 and 20). The whole seedlings died under these conditions. However, the independent *pip2;5-5* mutant did not show this phenotype (Fig. 19). Nevertheless, it was tested via complementation, whether there could be any correlation of salt sensitivity and *pip2;5* knockout. Eventually a genomic construct encompassing the whole *PIP2;5* gene could not complement the salt sensitive phenotype of *pip2;5-1* (see Annex 2 which focuses on observations regarding *pip2;5* mutants) indicating that *PIP2;5* is at least not directly responsible for the salt sensitivity observed. Indeed, *pip2;5-1* contains additional T-DNA inserts, as shown by Southern blotting (Results 3.2.2, Fig. 16), which likely contribute to the observed phenotype.

In addition, two independent *pip2;3* mutants also show water stress sensitivity. In case of mild salt stress (50 mM NaCl) no differences in growth were observed for any of the *pip2;3* mutants. However, *pip2;3* mutant leaves were found to be altered in case of severe salt stress (100 mM NaCl; Fig. 20 and 21). Indeed, when grown on 100 mM NaCl containing medium *pip2;3* seedlings become chlorotic and the leaf phenotype observed was correlated with a tendency for reduced root elongation (Fig. 19 and 21) indicating a severe damage on 100 mM NaCl plates. Importantly, in our conditions, *pip2;3* mutants showed an exclusively enhanced salt sensitivity since no phenotypical differences were observed when plants were grown under osmotic stress provoked by 200 mM sorbitol (Fig. 19 to 21). Since sorbitol can be metabolized by the plant, osmotic stress exerted by mannitol has also been tested for *pip2;3* mutants and results were similar to sorbitol (data not shown). Thus, *pip2;3* knockouts are exclusively sensitive to salt stress among *pip2* mutants, but not to purely isoosmotic stresses.

Regarding other mutants although no obvious phenotypes were observed, it is noteworthy that with 100 mM NaCl the final measured root length of *pip2;1* mutants was always lower than that of the wild-type. In fact, the double mutants tested, *2;2-3/2;1-2* and *2;1-2/2;4-1*, also showed the tendency for reduced root elongation that was observed for *pip2;1* single mutants under severe salt stress (Fig. 19). The root phenotype was more pronounced for *2;1-2/2;4-1*, however, the whole plants were also damaged including chlorosis of the leaves (Fig. 20). In addition, *2;1-2/2;4-1* double mutant developed less or shorter lateral roots in case of salt stress (Fig. 20). In comparison, osmotic stress imposed by 200 mM sorbitol did not lead to any reduced root elongation or visible phenotypical alteration in the conditions tested (Fig. 19 and 20).

**Figure 20. Growth of *pip2* single mutants under various water stresses show differential sensitivity.** *Arabidopsis thaliana* wild-type (WT) and *pip2* mutants were germinated on vertical MS gelrite plates and 4-day-old seedlings were then transferred to vertical gelrite plates containing various solutes (50 or 100 mM NaCl as well as 200 mM sorbitol) to imposed water stress. Seedlings were further grown for 7 days and subsequently photographed.

**Figure 21. Growth of *pip2;3* mutants is sensitive to salt stress.**

Root elongation and plant phenotype of *pip2;3* T-DNA insertional mutants and wild-type seedlings grown under various water stress conditions. Seeds were germinated on control medium and 4-day-old seedlings were transferred to vertically oriented plates containing control medium or control medium supplemented with different concentrations of NaCl or sorbitol to account for ionic and osmotic stresses. Seedlings were further grown for 7 days and root elongation was recorded daily (a to d). Wild-type and *pip2;3* mutant plantlets were photographed at the end of the treatment (e to f). Data in a, b, c and d are the means  $\pm$  SD of measurements from six individual plants. Experiments were repeated five times. (a, e) controls; (b, f) 50 mM NaCl; (c, g) 100 mM NaCl and (d, h) 200 mM sorbitol.

### 3.3.2 Morphological analyses of *pip2* mutants

Although most *pip2* mutants did not show any obvious visible phenotype under favorable growth or water stress conditions, a closer analysis of the root morphology has been carried out. Thus, roots of wild-type and *pip2* mutant seedlings grown under various conditions were observed by stereomicroscopy as well as confocal microscopy (LSM 510, Helmholtz Zentrum München-Institute of Pathology).

**Figure 22. Stereomicroscopy images of WT and *pip2* mutant root seedlings.**

Wt and *pip2* mutant seeds were germinated on MS-gelrite control medium and 4-day-old seedlings were transferred to vertically oriented plates containing MS-gelrite control medium or MS-gelrite control medium supplemented with 100 mM NaCl or 200 mM sorbitol. Seedlings were further grown for 7 days, visualized with a stereomicroscope and photographed. Insertional *pip2* mutants did not show any root alterations with respect to the wild-type. As a representative example *pip2;1-2* is shown.

However, no morphological alterations could be observed between wild-type and *pip2* mutant plants under both standard and water stress conditions (Fig. 22). As expected, differences were observed between plants grown on standard medium and water-stressed plants. Thus, lateral root growth as well as root hair development was reduced, however, the morphology of the *pip2* mutants was affected in a similar way than the wild-type (Fig. 22).

### 3.3.3 Leaf water relations

Plant water relation is a complex process involving both below- and above-ground organs. In leaves, water loss via transpiration is the most critical parameter. It is mostly regulated by closure and opening of stomata, but also depends on water supply. To check whether PIP2 proteins play a role in regulation of water loss through the leaves, two independent types of experiments were performed. First, the rate of the loss of water from detached rosettes was recorded for *pip2* mutants and wild-type. Second, the transpiration and water use efficiency of selected mutants was analyzed.

#### 3.3.3.1 Loss of water from detached rosettes

In order to record the loss of water from detached leaves, the aerial portion of three-week-old *pip2* mutant plants and wild-type controls grown on soil were removed from the roots, weighed, and the decline in fresh weight of the rosette leaves was measured for a period of four hours (Fig. 23 and 24).

The measured initial fresh weight was used to investigate differences in above ground part biomass. No significant differences could be observed in the initial fresh weight of 3 week-old plants grown on soil (Fig. 23).

**Figure 23. Rosette leaves fresh weight.**

Rosette of three-week-old control and *pip2* mutant plants were detached and weighed. Bars represent fresh weight as a mean  $\pm$  SD obtained from 4 individual plants. Experiments were repeated 3 times (or only twice for *pip2;2-3*, *pip2;2-4*, *pip2;6-2* and *pip2;8-1*).

The loss of water from detached leaves was then recorded under controlled temperature, light and humidity (Method 2.2.1.7). A gradual decline in leaf water content can be observed and this rate of leaf water loss was compared between mutants and wild-type. In this experiment, since the leaves are detached from the roots there is no water coming in and the rate of water loss is solely determined by the properties of the leaves such as stomatal conductance and leaf morphology. However, these analyses indicated that *pip2* single mutants did not alter the rate of water loss with respect to the wild-type (Fig. 24a to f). Although the *pip2;3-2* mutant deviated from the wild-type in showing an increased water loss, this phenotype was not confirmed by the independent *pip2;3-1* mutant.

However, detached-rosette assay showed that in the *pip2* double mutants decline in leaf water loss was slightly lower in comparison to wild-type (Fig. 24g and h). Although, this decline was relatively low (5%), it was significantly observed all over the time course of the experiment (Fig. 24g and h).

**Figure 24. Water loss using detached rosette assay.**

Relative water loss from rosette of three-week-old mutants and wild-type plants was assessed. Rosettes were detached and weighed every hour for 4 hours. Decline in fresh weight was expressed in percentage of the initial fresh weight. Percentage of initial fresh weight is displayed as mean  $\pm$  SE obtained from three independent biological experiments ( $n = 3$  with 4 separate plants for each experiment). The asterisks indicate statistically significant differences, as determined by two-tailed distribution student's  $t$  test assuming unequal variance (\*\*\*)  $p < 0.005$ ). (a to f) *pip2* single mutants. (g) *pip2;2-3/pip2;1-2* and (h) *pip2;1-2/pip2;4-1* double mutants.

### 3.3.3.2 Transpiration, stomatal conductance, net photosynthesis and water use efficiency measurements

To analyze potential additional effects of *pip2* loss-of-function on plant water relations, several physiological traits such as transpiration and water use efficiency were also measured. For these analyses, *pip2;1-2*, *pip2;2-3* and *pip2;2-3/pip2;1-2* knockout mutants were chosen. First, they represent mutants of abundantly expressed aquaporins in both roots and leaves. Second, the slightly lower water loss observed for the double mutant suggested PIP2;1 and/or PIP2;2 may play an important role in plant water relations.

Measurements were done on three-week-old *pip2* mutant plants and wild-type controls grown on soil under either well-watered or water deficit conditions (Table 6). Water deficit condition was achieved by withholding watering four days before the measurements. Transpiration, stomatal conductance, net photosynthesis and water use efficiency were measured. Leaves were then cut and leaf area and leaf fresh and dry weight were determined (Table 6). In comparison to well-watered conditions, values under water deficit conditions were only little lower indicating a mild stress (Table 6).

There was no effect of *pip2* knockouts on leaf area or mass either under well-watered or water deficit conditions. Similarly, transpiration was not affected. Nevertheless, it was interesting to note that under well-watered conditions, net photosynthesis and water use efficiency was slightly lower in the single mutants than in wild-type plants (Table 6). Surprisingly, the double mutant was comparable to wild-type plants (Table 6).

In general, our measurements were in agreement with those obtained by Martre et al. (2002) who showed that stomatal conductance, leaf transpiration rate as well as leaf hydraulic conductance were not affected in PIP1 and PIP2 single and double antisense plants. Nevertheless, more replica are needed to confirm these results due to the high variability of the individual measurements.

**Table 6. Transpiration, stomatal conductance, net photosynthesis and water use efficiency measurements.**

Leaf fresh weight (LFW), leaf dry weight (LDW), leaf (LWC) and relative water content (RWC), leaf area, transpiration (E), Vapor-Pressure-Deficit (VPD), stomatal conductance (gH<sub>2</sub>O), net photosynthesis (NP) and water use efficiency (WUE) were measured for wild-type and insertional *pip2* knockout mutant plants. Measurements were done using single plants (three-week old) grown in soil under well-watered or water deficit conditions. Values are means  $\pm$  SE. n = number of individual plants. Environmental conditions were: 25°C, 53% relative humidity, light intensity was about 300  $\mu\text{mol m}^{-2} \text{s}^{-1}$  and CO<sub>2</sub> abs. 380 ppm.

### 3.3.4 Isotope tracing in plant water relations – deuterium content in leaf water

Many efforts have been made in the past to investigate water transport in plants. The use of stable isotopes techniques in plant research is increasing as the isotopes can serve as very valuable tracers allowing the nondestructive investigation of whole organisms and their interactions with biotic and abiotic environments. The isotopic content of leaf water (both D and  $^{18}\text{O}$ ) and its progressive enrichment due to e.g. transpiration and leaf compartmentation has been modeled (see below) to assess these processes in plant ecology and physiology. Thereby, the natural enrichment of D content in leaves was determined as well as changes of steady state after application of water with artificially enhanced D or  $^{18}\text{O}$  content (Flanagan et al., 1991; West et al., 2006; Santrucek et al., 2007).

In contrast to these studies, I wanted to establish a dynamic tool using source water with artificially enhanced D content as a tracer to study the kinetics of water uptake and flux from roots into the aerial parts until a *new* equilibrium is reached. A particular advantage in contrast to most other techniques such as root exudation, pressure chamber or pressure bombs was that this approach would be non-invasive during the experiment.

Thus, water transfer into the rosette leaves was followed in a 24 h kinetic study by measuring the D translocation into whole rosette leaf water. Any genetic change e.g. an aquaporin knockout that will influence the water relations, may alter fluxes and thus the rate of establishing the new equilibrium.

#### 3.3.4.1 Theory: Modeling leaf water isotope content

The isotopic composition of leaf water is generally different from the source water taken up by the roots and may become enriched or depleted in D depending on the relative humidity of the atmosphere, the D content of the soil water and that of the atmospheric moisture. Craig and Gordon (1965) established a model that depicts the stable isotope fractionation processes occurring during evaporation of water from the ocean. The processes result in a D enrichment of surface ocean water. The model was adapted for water transpired from a leaf and shown to be applicable to describe the D content of plant leaf water (Wershaw et al., 1966; Flanagan et al., 1991; Roden and Ehleringer, 1999a; Barnes et al., 2004).

The leaf water model considers the following processes (Fig. 2):

- Water evaporation from the leaf (leaf surface/ sub-stomatal spaces) into leaf intercellular air spaces. The water vapor in this layer is in thermodynamic equilibrium with the leaf water.

- Diffusional and turbulent transport of water vapor from this interface through stomata to the atmosphere. It was assumed that the turbulent transport was negligible in our experimental setting<sup>1</sup>.

Fractionation factors describe the isotopic effects in the two processes. The equilibrium fractionation factor  $\alpha_{eq}$  determines the relationship between the liquid water and water vapor in equilibrium:

$$\alpha_{eq} = R_l / R_v \quad (1)$$

where R is the molar ratio of the heavy and light isotope, i.e. D/H, and the subscripts l and v refer to liquid and vapor water, respectively. In the above definition it is assumed that the air is saturated with water vapor and that the liquid and vapor are at the same temperature. These conditions are satisfied for a leaf where water vapor in the intercellular air spaces is in equilibrium with leaf cell water. Majoube (1971) has measured the fractionation factor over a wide temperature range:  $\alpha_{eq} = \text{Exp}(24844/T^2 - 76.248/T + 0,052612)$  (with T temperature in Kelvins). This expression was used to calculate values for  $\alpha_{eq}$ .

The kinetic fractionation factor  $\alpha_{kin}$  governs (beside the other mentioned parameters) the diffusional transport. It is defined as the ratio of the diffusion coefficients for water vapor molecules containing the light and heavy isotopes,

$$\alpha_{kin} = D_{\text{}^1\text{H}_2\text{O}} / D_{\text{}^1\text{H}^2\text{HO}} = D/D' \quad (2)$$

The different diffusion coefficients mainly result from the different molecular masses. In air this kinetic fractionation factor  $\alpha_{kin}$  has been measured to be  $\alpha_{kin} = 1.025$ , indicating a 1.025 fold faster diffusion of H<sub>2</sub>O vs. HDO (Merlivat, 1978). The transpirational flux due to diffusion is described according to Fick's law

$$Flux = -Diffusionfactor \cdot \frac{\partial Concentration}{\partial Distance} \quad (3)$$

and thus, the transpirational flux E of the isotopically light water can be described as:

$$E = D \cdot \frac{\partial(e_i - e_a)}{\partial x} \quad (4)$$

---

<sup>1</sup> Several attempts have been made in modifying the model to account for turbulent conditions in a boundary layer and for boundary layer effects (e.g. Flanagan et al., 1991; Farquhar et al., 1989). The authors suggested that taking these modifications into account could improve the predictions for the leaf water D content. However, these parameters were shown to be negligible to the well ventilated *Arabidopsis* system, since the model predicted the actual leaf water D content quite reasonably (see below, verification of the model).

with  $e_i$  and  $e_a$  indicating the partial pressures of total water vapor in the leaf intercellular air spaces and the ambient air, respectively. The small portion of deuterated water can be neglected and, hence,  $e_{i/a} [\text{H}_2\text{O}]$  is well approximated by  $e_{i/a} [\text{total water}]$ .  $P$  is the total air pressure, thus  $e_{i,a}/P$  indicates the concentration of water in the two gas phases of compartments  $i$  and  $a$ . A similar equation can be written to describe evaporation of heavy isotopes molecules (HDO):

$$E' = D' \cdot \frac{\partial(R_i e_i - R_a e_a)}{\partial x} / P \quad (5)$$

However, the partial pressure of deuterated water vapor in the leaf intercellular air spaces and the ambient air are only a fraction of  $e_i$  and  $e_a$ . Accordingly, they are to be multiplied by the molar ratios  $R_i$  and  $R_a$  of the heavy and light (i.e. approximately total) isotopes of water vapor in these compartments.

These equations depict the flux of light or heavy isotopes molecules transpired by the leaves. Hence, the isotopic composition of water evaporating and transpiring from a leaf  $R_{\text{trans}}$  can be described as the ratio of the fluxes of the heavy ( $E'$ ) and the light ( $E$ ) isotopes:

$$R_{\text{trans}} \approx \frac{E'}{E} = \frac{1}{\alpha_{\text{kin}}} \frac{(R_i e_i - R_a e_a)}{(e_i - e_a)} = \frac{1}{\alpha_{\text{kin}}} \frac{\left( \frac{R_{\text{leaf}}}{\alpha_{\text{eq}}} e_i - R_a e_a \right)}{(e_i - e_a)} \quad (6)$$

with  $R_i = \frac{R_{\text{leaf}}}{\alpha_{\text{eq}}}$  assuming water vapor in the intercellular air spaces in equilibrium with the leaf water.

Resolving equation 6 for  $R_{\text{leaf}}$  produces equation 7:

$$R_{\text{leaf}} = \alpha_{\text{eq}} \left[ \alpha_{\text{kin}} R_{\text{trans}} \left( 1 - \frac{e_a}{e_i} \right) + R_a \left( \frac{e_a}{e_i} \right) \right] \quad (7)$$

Since the air in the intercellular spaces is saturated with water vapor,  $e_i$  will be maximal (at the respective constant temperature). Hence,  $e_a/e_i$  equals the relative humidity  $h$  of the ambient air. The equation is then expressed in its simpler form describing  $R_{\text{leaf}}$  as being dependent on  $R_{\text{trans}}$ ,  $R_a$ , and the ambient humidity:

$$R_{\text{leaf}} = \alpha_{\text{eq}} \left[ \alpha_{\text{kin}} R_{\text{trans}} (1 - h) + R_a \cdot h \right] \quad (8)$$

It has to be noted that measuring the isotopic composition of the water of one leaf or even of a collection of leaves like the rosette leaves in this study and using this value in equation 8 treats the leaf water as being ideally mixed, which is a simplified view. Indeed, it has been

shown in various experiments that the model of Craig and Gordon predicts a greater isotopic enrichment than was actually observed in leaf water (Flanagan et al., 1991; Roden and Ehleringer, 1999a). The possibility that different fractions of water within a leaf are not necessarily uniform has been inferred to explain this discrepancy. It was suggested that the differences might result from unfractionated water in leaf tissue. Accordingly, several studies introduced a separation into two compartments reflected by the xylem vessels and the major rest of the leaf volume represented by the mesophyll cells. The portion of unfractionated water has often been calculated to be 13% to 30%. However, in our experimental set-up this portion was evaluated to be about 3% (data not shown) and the model predicted the actual leaf water D content quite reasonably (see below, verification of the model). Consequently, such effects were considered negligible.

According to equation 8 the isotopic composition of leaf water  $R_{\text{leaf}}$  depends only on the isotopic composition of the transpiration as long as the ambient humidity and isotopic composition of the atmosphere are constant.

Although it is true for a freely evaporating surface (like ocean), in case of a plant, water can exit the leaves not only by transpiration but also via the phloem flux back to lower leaves or roots (Fig. 2). Consequently, for a plant, the steady state of  $R_{\text{leaf}}$  described by equation 8 should be modified to account for water loss via phloem. If we call  $R_{\text{loss}}$  the total water loss by the leaves, then:

$$R_{\text{loss}} = R_{\text{phloem}} \cdot f + R_{\text{trans}} (1 - f) \quad (8a)$$

where  $R_{\text{phloem}}$  is the isotopic composition of phloem water and  $f$  is the fraction of the total lost leaf water attributed to phloem water flow.

The steady-state of  $R_{\text{leaf}}$  will be reached as soon as  $R_{\text{loss}}$  is equal to  $R_{\text{xyl}}$ , which will be the case when the isotopic composition of the water exiting the leaves (transpiring water and phloem water) will be the same as that of the resupplying water taken up by the roots through the xylem,  $R_{\text{xyl}}$ .

Assuming that phloem water takes on an isotopic composition identical to that of leaf water,  $R_{\text{phloem}}$  equals  $R_{\text{leaf}}$ . Thus, from eq. 8 and 8a follows equation 9 which describes the isotopic composition of the leaf water in steady state depending on the isotopic composition of the source water  $R_{\text{xyl}}$ :

$$R_{leaf} = \frac{1}{(1/\alpha_{eq}) \cdot (1-f) + f \cdot \alpha_{kin} \cdot (1-h)} \cdot (\alpha_{kin} (1-h) R_{xyl} + (1-f) h \cdot R_a) \quad (9)$$

where  $R_{xyl} = R_{loss}$

If one transfers hydroponically grown plants to a new medium containing enhanced deuterium content, the isotopic composition of the leaf water  $R_{leaf}$  and that of the total water lost from the leaves  $R_{loss}$  is continuously changing until a new steady state is reached.

This temporal change of the isotopic composition of leaf water  $dR_{leaf}/dt$  can be expressed by equation 10.

$$\frac{dR_{leaf}}{dt} = (R_{xyl} - R_{loss}) q_{leaf} \quad (10)$$

where  $dR_{leaf}/dt$  is proportional to the relative turnover of leaf water  $q_{Leaf}$  ( $q_{Leaf} = Q/V_{leaf} [s^{-1}]$  with  $Q$ : leaf water turnover and  $V_{leaf}$ : leaf water volume) as well as to the difference of the isotopic content of the incoming water  $R_{xyl}$  and isotopic content of the lost water comprising transpiring water and water that flows back to the root via the phloem.

$R_{xyl}$  will be very close to that of the source water in soil or in a hydroponic tank. Water exchange occurring along the path through the xylem with the radially surrounding cells is rather quick and is assumed to be negligible in terms of volume in comparison to the high axial flow of water. Therefore, the water arriving in the leaf can be assumed to be isotopically equal to the soil water or water in the hydroponic tank:  $R_{xyl} = R_{soil}$  (Fig. 2).

Finally, through a substitution of  $R_{loss}$  (eq. 8a) and  $R_{trans}$  (eq. 8) into equation 10, the differential equation reads:

$$\frac{dR_{leaf}}{dt} = \left[ R_{xyl} - \left( (1-f) \cdot \left( \frac{1}{\alpha_{kin}} \frac{R_{leaf} / \alpha_{eq} - h \cdot R_a}{1-h} \right) + f \cdot R_{phloem} \right) \right] \cdot q_{leaf} \quad (11)$$

The solution of this differential equation describes the temporal change of the isotopic content of rosette leaves water which approaches the new steady-state  $R_{leaf,SS}$  (identical to  $R_{leaf}$  in equation 9) for high values of  $t$ :

$$R_{leaf}(t) = R_{leaf,SS} (1 - \exp(-aq_{leaf}t)) + R_{leaf,0} \exp(-aq_{leaf}t) \quad (12)$$

$R_{leaf,0} = \text{Starting value}$

$$R_{leaf,SS} = \text{steady state} = \frac{1}{(1/\alpha_{eq})(1-f) + f \cdot \alpha_{kin} \cdot (1-h)} \cdot (\alpha_{kin} \cdot (1-h) \cdot R_{xyl} + (1-f)h \cdot R_a)$$

$$a = \frac{(1/\alpha_{eq}) \cdot (1-f)}{\alpha_{kin} \cdot (1-h)} + f$$

$q = \text{water turnover rate}$

$t = \text{time}$

This equation was used to model the isotopic enrichment of rosette leaves water in the experiments described below after an intentional increase in source water D content in order to determine the relative turnover of leaf water  $q$  (equaling relative xylem flux) and the fractionation factor  $f$  (approximating phloem back flow).

### 3.3.4.2 Evaluation of the leaf water isotope model

The validity of the model was tested for the small, herbaceous model plant *Arabidopsis thaliana*. Equation 9 was to be used to model the steady-state isotopic content of leaf water for *Arabidopsis* rosettes before and after raising the D concentration of the tank water of hydroponically grown plants.

To be able to compare different plants/ genotypes, several parameters that might potentially influence water relations like light intensity, humidity and temperature had to be maintained constant and measured throughout the experiment. Thus, all experiments were done in a sun simulator with carefully controlled conditions (see Method 2.2.1.9). As mentioned above (see theory), the isotopic composition of the atmospheric water vapor influences the stable isotope composition of leaf water. According to equation 9 the steady-state of  $R_{leaf}$  will also vary with  $R_a$ . Therefore, the water vapor in the air of the sun simulator was collected and its isotopic content measured. It had in the sun simulator a  $\delta D$  value in the range of -120‰ to -150‰.

A prerequisite for applying the model is that the source water  $R_{xyl}$  equals a constant  $R_{tank}$  of the water supplied via the hydroponic solution. If the roots are submerged into D-enriched water, it is assumed that the water in the xylem that will supply the leaves will have the same isotopic composition as the tank water after a rather short lag phase. To control and measure the actual deuterium content of  $R_{xyl}$  that feeds into the model equations, water samples were collected both prior and after addition of deuterium in the tank water as well as throughout the experiment. The measurements demonstrated that tank water was well maintained throughout the experiment and that only minor changes occurred in tank water isotopic composition over the course of the experiment (Fig. 25).

Two steady-state situations occurring in our experiments were tested:

- Steady-state of plants grown in regular medium (i.e. starting point of the experiment)
- Steady-state after adding deuterium in the medium (considerable increase).

and the measured values compared with the value predicted by equation 9.

Three-week-old *Arabidopsis* plants were transferred to a fresh medium enriched in deuterium. For the two steady-states, the modeled isotopic content of leaf water was in good agreement with the measured values when the fractionation factor  $f$  was fitted to a value of 0.15 (Table 7). The values predicted by the Craig and Gordon model were slightly different from the measured values demonstrating the improvement by the introduction of  $f$ .

**Table 7. Isotopic composition of leaf water ( $\delta D$ , ‰) of hydroponically grown *Arabidopsis thaliana* plants.**

Isotopic content of leaf water was measured on samples collected right before starting the experiment (prior addition of  $D_2O$  in the medium) and at different time point after addition of  $D_2O$  in the medium. Environmental conditions were: 22°C, 50% relative humidity while light intensity was about  $475 \mu mol m^{-2} s^{-1}$ . Isotopic content of water vapor was -130‰ and fractionation factor  $f$  fitted to 0.15.

Genotype	Initial steady state (time 0)				Final steady state (after 24 hours)			
	Measured source water	Measured	Phloem model	C & G model	Measured source water	Measured	Phloem model	C & G model
WT	$-77.5 \pm 0.1$	$-20.7 \pm 5$	-22.5	-17.1	$311.4 \pm 1.7$	$212.3 \pm 9.3$	208.8	198.7
2;2-3	$-77.7 \pm 0.1$	$-19 \pm 4.6$	-22.6	-17.2	$307.8 \pm 2.4$	$203.3 \pm 9.7$	206.6	196.7
2;2-3/ 2;1-2	$-77.8 \pm 0.1$	$-21.3 \pm 3$	-22.7	-17.3	$305.2 \pm 1.3$	$209 \pm 5.6$	205.1	195.3

Furthermore, the second situation could be used to test the time required for leaf water to reach the new isotopic steady-state. The dynamic changes in leaf rosette D content were recorded over 24 h and modeled using equation 12 (Method 2.2.1.9). This experiment showed that the leaf isotopic steady-state was reached after the plants had been exposed to the new conditions for approximately 6 hours (Fig. 25). It is known that the relative humidity has an important impact on the model (see above, theory), because it influences the transpiration rate to the atmosphere. The model using 50% humidity as a parameter fits well to the measurement of the experiment carried out at 50% relative humidity (Figure 25, blue curve). However, changing the relative humidity parameter can drastically modify the steady-state (Fig. 25, red and green curve). Indeed, increasing the relative humidity will tend the leaf isotope content to the values of the atmospheric water vapor (Fig. 25, red curve). In a similar way, low humidity will shift the D content of the leaf water to the values of the xylem water and will increase the leaf isotope content (Fig. 25, green curve).

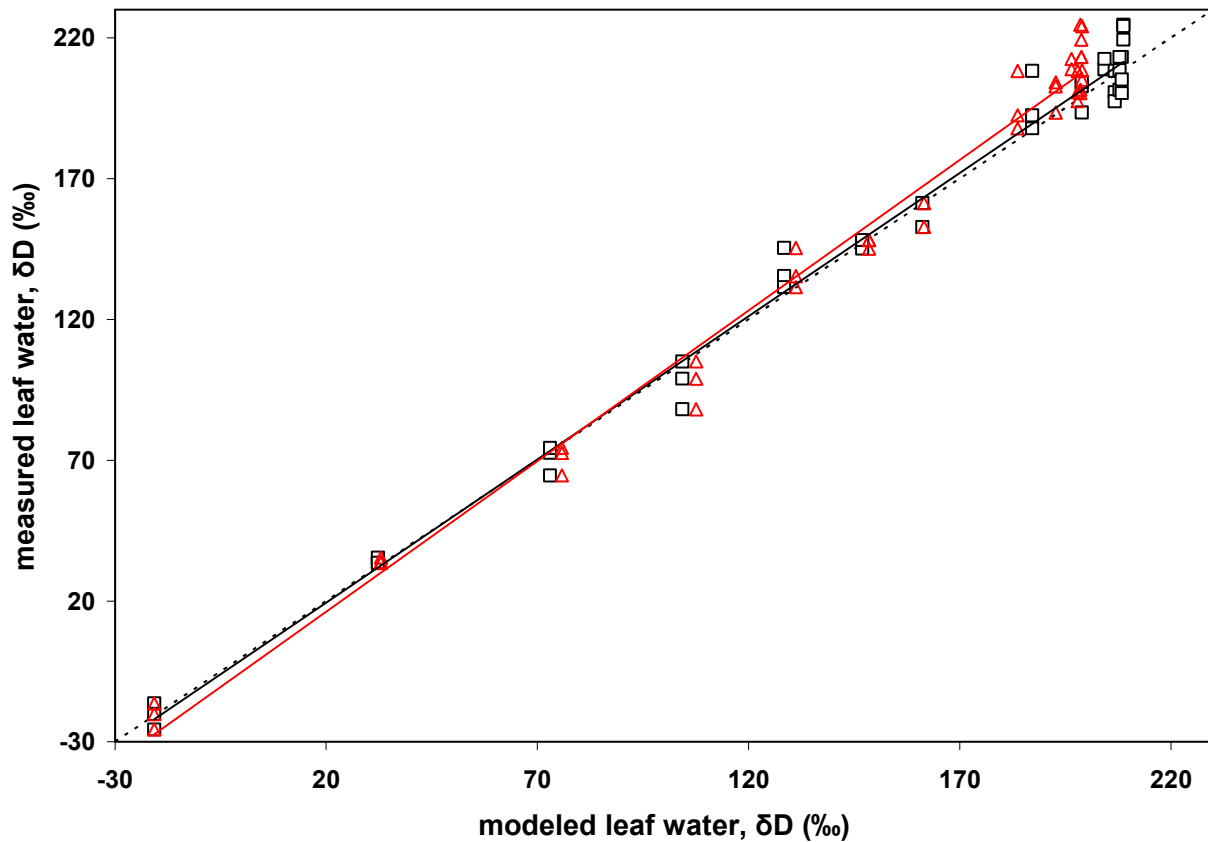

**Figure 25. Modeling of isotopic content in leaf water of hydroponically grown *Arabidopsis* plants.**

The different curves show the influence of relative humidity (RH) on the model. Solid circles are means ( $n = 3$ ) and SD of measured isotopic content of rosette leaves water (some SD are contained within the symbol). Phloem fractionation factor  $f$  was 0.15 and  $q$  was  $0.0079 \text{ min}^{-1}$ .

The steady-states were well predicted by the modified model (Table 7). It was further investigated whether the dynamic change of isotopic content of the leaf water over time were in good agreement with the kinetic predictions of the model using equation 12. The comparison between measured and modeled isotopic content of leaf water revealed very good model predictions all over the course of the experiment allowing to accurately calculate the relative xylem flux  $q$  (Fig. 26;  $q = 0.0079 \text{ min}^{-1}$ ). Moreover, the model including a phloem fraction exiting the leaves (here  $f = 0.15$ ) slightly improved the predicted values (slopes 1.0172 vs. 1.0694 in comparison to a perfect match of 1.0000; Fig. 26). The improvement due to the introduction of the fractionation factor  $f$  was even more pronounced under conditions of high humidity. Indeed, although the Craig & Gordon model predictions were still in reasonable agreement with measured values in case of experiments done with 50% humidity

(Fig. 26; red line), a strong discrepancy with measured values was observed in case of high humidity (Fig. 27).

**Figure 26. Relationship between the  $\delta D$  of modeled and measured leaf water in *Arabidopsis* plants.**

*Arabidopsis* wild-type plants were grown in hydroponic medium in a sun simulator. Relative humidity was set to 50% (for other environmental conditions, see Method 2.2.1.9). Black squares and red triangles represent the measured leaf  $\delta D$  over the course of the experiment (24 h) plotted against the phloem fractionated (with  $f = 0.15$ ) and the original Craig & Gordon modeled values, respectively. In both model, the calculated relative turnover of leaf water  $q$  was  $0.0079 \text{ min}^{-1}$ . Three plants were measured for each time points with 14 time points. The equation for the regression lines was  $y = 1.0172x - 0.9236$  ( $r^2 = 0.9900$ ) and  $y = 1.0694x - 5.18$  ( $r^2 = 0.9867$ ) for the phloem fractionated (black line) and the original Craig & Gordon model (red line), respectively. The stippled line represents a 1:1 relationship.

In case of high humidity, transpiration is rather low and the fraction of phloem water flowing back is increasing in comparison to high transpiration situation. Indeed, in such an experiment, assuming a higher fraction  $f$  of water circulating via the phloem considerably improved the model prediction. By model fitting one can get a guess of the water fluxes in the phloem additional to the water fluxes in the xylem. It is important to note that the estimates of the phloem fluxes and their accuracies depend on model concept. Further experiments have to clarify, how close the concept of our model is to reality.

Figure 27 illustrates the utility of the adjusted model which fits well with the measured values when assuming a phloem fraction  $f = 0.7$  and improves the Craig & Gordon derived leaf model. The Craig & Gordon model frequently predicts higher isotopic enrichment at the initial steady-state under natural conditions, while it will underestimate the experimental values after addition of deuterium in the source water in the experimental system used here (Fig. 27; see also Fig. 25 and 26).

**Figure 27. Modeling of isotopic content in leaf water of hydroponically grown *Arabidopsis* plants.**

Experiment was done under high humidity (85%) (for other environmental conditions, see Method 2.2.1.9). Triangles are means ( $n = 3$ ) and SDs of measured isotopic content of rosette leaf water. Using a phloem fractionation factor of 0.7, the modeled values predictions were in good agreement with the experimentally measured values while the Craig & Gordon (C & G) model underestimated the isotopic enrichment of leaf water.

To be able to compare different plant genotypes the influence of several plant-intrinsic parameters such as root and leaf fresh weight on the isotopic composition of bulk leaf water had to be examined as well.

After addition of  $D_2O$  to the hydroponic medium, the increase of D content in rosette leaves as well as the mass of the extracted leaf water (as a measure for the leaf water volume) and the individual root fresh weights were monitored during a period of 24 h. Clearly, the measured D content in the leaves was independent from both leaf and root masses at all time

points (Fig. 28a and b). There was also no correlation of leaf D concentration with the ratio of leaf to root mass (data not shown).

Plants were grown hydroponically and their roots were fully immersed in water. Thus, root water uptake was not limiting in our conditions, i.e. different root masses did not lead to different rates of uptake. The model equation 12 only allows the fitting of  $q$  ( $Q$ / leaf mass) and fractionation factor  $f$ . Therefore, it was very important that the leaf isotopic content was independent from the water volume of rosette leaves, i.e. a larger rosette had taken up equivalently more water (xylem flux  $Q$ ) from the medium at a certain time point to reach the same concentration of deuterium. Consequently, this feature was decisive for the applicability of the model and allowed comparing different plants irrespective of deviating leaf masses and extracting the relative flux  $q$ . The major properties influencing the model parameters  $q$  and  $f$  are the genetic and/or physiological traits of the plants.

Nevertheless, it is important to note that measurements of root fresh mass, leaf fresh and dry weight, and shoot/root ratio did not reveal mean differences between wild-type and several *pip2* mutant plants *per se* (*pip2;1*, *pip2;2*, *pip2;4-1* and *pip2;2-3-pip2;1-2*; data not shown). Eventually, growth is neglected in the short time frame of analysis.

**Figure 28. Influence of leaf water volume or root fresh weight on the isotopic content of *Arabidopsis* rosette leaves water.**

At different time points, *Arabidopsis* wild-type plants were collected and their roots weighed. Water was extracted from rosette leaves and its volume and isotopic content measured. (a) Graphical display of the relation between leaf water volume or root fresh weight and the leaf  $\delta D$ . Bars, circles as well as squares represent means  $\pm$  standard deviations ( $n = 3$ ). (b) Leaf water volume, root fresh weight and leaf  $\delta D$  of individual plants harvested at different time points.

### 3.3.4.3 Comparison of deuterium content in rosette leaves water of wild-type and *pip2* mutants

Using this set-up and applying the developed model the dynamic change in isotopic content of rosette leaves, several *pip2* mutants were measured to investigate the involvement of PIP2 aquaporins in plant water transport. The *pip2;1* and *pip2;2* single mutants as well as *pip2;2-3/ pip2;1-2* double mutant were analyzed. As indicated above, *PIP2;1* and *PIP2;2* represent highly expressed isoforms in roots and leaves. In addition, their cellular expression profile (i.e. abundant in root cortex, endodermis as well as vascular tissue throughout the whole plant) together with the slight alteration of leaf water loss observed in double mutants may suggest a role in water transport between cells and tissues. Additionally, *pip2;4-1* single mutant was also analyzed. Although *PIP2;4* did not show expression in the leaves, its interesting root expression pattern (see Results 3.1) prompted us to analyze this mutant.

Figure 29 shows a typical experiment in which *pip2;2-3* single mutant exhibit a reduced leaf water isotopic enrichment in comparison to wild-type and *pip2;2-3/ pip2;1-2* double mutant plants.

**Figure 29. Comparison of deuterium translocation into rosette leaves water of wild-type and *pip2* mutants.** Increase of the D content in rosette leaves water of *pip2;2-3* single mutant and *pip2;2-3/ pip2;1-2* double mutant was compared to that of wild-type plants (see Method 2.2.1.9 for environmental conditions). For each time points, symbols represent means  $\pm$  standard deviations of 3 independent plants. In comparison to wild-type and *pip2;2-3/ pip2;1-2* mutant plants which exhibited a similar relative water turnover ( $q = 0.0079 \text{ min}^{-1}$  and  $q = 0.0083 \text{ min}^{-1}$ , respectively), *pip2;2-3* mutant showed a lower deuterium enrichment with a relative water turnover  $q = 0.0064 \text{ min}^{-1}$ . Phloem fractionation factor were  $f_{wt} = 0.15$ ;  $f_{2;2-3/2;1-2} = 0.15$  and  $f_{2;2-3} = 0.10$ .

Both *pip2;1* and *pip2;2* single mutants exhibited a 15-20% slower increase of the D content (i.e. lower leaf water turnover  $q$ ) in comparison to wild-type controls. In contrast, *pip2;4-1* did not show this reduction (Fig. 30). These data could suggest that a similar or even higher reduction would be observed in the *pip2;2-3/pip2;1-2* double mutants. However, surprisingly no reduction was observed for the double mutant indicating a phenotypic recovery (Fig. 29 and 30).

It is noteworthy that no significant differences were found for the fractionation factor  $f$  (data not shown).

**Figure 30. *pip2* single mutants exhibit a reduced leaf water translocation.**

Increase of the D content in rosette leaves water of *pip2;1* and *pip2;2* is slower compared to that of the wild-type and a *pip2;2-3/pip2;1-4* double mutant. Bars represent means  $\pm$  standard deviations ( $n = 2$  for *pip2;1-2* and *pip2;2-3/pip2;1-2*, while *pip2;4-1* was done only once). Bar for *pip2;2* represent means of two independent *pip2;2* mutants (*pip2;2-3* and *pip2;2-4*) analyzed twice each.

### 3.3.5 Root gravitropism of *pip2* mutants

In addition to regular root growth, gravistimulated bending of root growth was also analyzed. Gravity provides a cue for downward orientation of plant roots and, hence, contributes to optimal utilization of available resources. Rotating seedlings grown on vertical agar plates by 90°C exerts a new stimulus that leads to a bending of the roots. All *pip2* single mutants were assessed for altered bending by this specific growth conditions requiring quick and differential growth to achieve bending and thus, the possible involvement of aquaporin-mediated water permeability. Seedlings were grown on vertical 0.5X MS-gelrite plates. Plates containing four-day-old seedlings were then gravistimulated and seedlings were photographed every 30 min for 8 h and then at 24 h (Fig. 31). Root bending was initiated after approximately 1 h for wild-type as well as *pip2* mutant plants. Although the bending angle kinetics were not measured, it was evident that the gravitropism response was not severely affected in any of the *pip2* mutant tested (Fig. 31).

**Figure 31. Gravotropism directs downward root growth in *Arabidopsis thaliana*.**

Four-day-old wild-type and *pip2* mutant seedlings were grown on vertical gelrite-based medium in the light and positioned horizontally (gravistimulated). A *pip2;1-2* mutants is shown as a representative example. After 1 h, the roots have initiated a downward gravitropic curvature. In all panels the gravity vector is directed downward.

### 3.4 Transcriptional analyses of *pip2* knockout mutants

A particular mutation of a gene may lead to disturbance of other processes which may involve the deregulation of genes from these pathways. A suitable means to analyze changes at the transcriptional level of many genes is array hybridization technology. Here, two array technologies were used to measure changes in gene expression in the mutants with respect to the wild-type. The aim was to identify processes which might be disturbed in various *pip2* mutants and to compare the potential changes among the different *pip2* mutants.

#### 3.4.1 Custom-made array covering target genes related to membrane transport

It is possible that the loss of individual *PIP2* may alter the natural expression of other endogenous aquaporins. In particular, it is important to know whether other *PIP* genes may be deregulated to compensate for a specific *pip2* loss-of-function, which, in turn, could influence the behavior of *pip2* mutant plants. Furthermore, the uptake and distribution of nutrients is directly linked to the bulk flow of water in the plant. Any transport across cellular membranes generates osmotic differences and thereby a driving force for the permeation of water. Thus, water and solute transport might influence each other. Previous analysis in roots have shown that transcription of aquaporins is highly sensitive to cation stresses and at the same time several members of other transporter families are deregulated (Maathuis et al., 2003). Analyses of *PIP2* expression indicated that all are present in roots (Results 3.1). Hence, the loss-of-function of any *PIP2* in the plant could lead to disturbance of the uptake and translocation or distribution of water and solutes.

Thus, the effect of *pip2* loss-of-function on other *MIP* genes as well as other transport processes was assessed at the transcriptional level in roots using a custom-made array. It harbored gene-specific DNA fragments of more than 500 genes encoding membrane proteins potentially mediating transports function as well as unrelated controls. Probes were designed and checked as previously described (Glombitza et al., 2004; Zhu et al., 2005) to ensure high specificity of the probes and to avoid cross-hybridization or provided by Eric van der Graaff, Sonja Hetfeld, Ulf-Ingo Flügge and Reinhard Kunze (Cologne, Germany; Unpublished data). The achieved probe specificity avoids e.g. also cross-hybridization of the closely related *PIP2;2* and *PIP2;3*, which are not distinguished by the Affymetrix ATH1 array (see below, Results 3.4.2; Affenzeller, 2003). A complete list of genes present on the array can be found in Supplementary Table 1.

Roots were harvested from wild-type and *pip2* mutant plants grown in hydroponic culture for three weeks. Two biologically independent replicates of twelve mutants and Columbia wild-type were analyzed in each case. In order to avoid a bias caused by additional T-DNA insertions in some mutants, replicates of independent mutant of the same *PIP2* gene were combined. Consequently, only genes consistently deregulated in both mutants were then seen as real changes.

The array was first evaluated by asking whether the knockout of a specific *PIP2* aquaporin may disturb the expression of other *MIPs* genes. Importantly, these analyses showed that in the conditions used all 35 aquaporin transcripts were detected in the plant roots. However, no significant changes in the transcript levels of *MIPs* were measured in the *pip2* knockout mutants with respect to the wild-type (Table 8). In particular, these results indicate that none of the single *pip2* mutations was compensated for by deregulation of other *PIP2* genes.

Movement of water is intricately linked to that of solutes or ions, which generate osmotic differences. Consequently, the array was also used to monitor transcriptional changes of membrane transport-related gene families (e.g. vacuolar ATPases, ABC transporters, sugar transporter, potassium channels, cyclic nucleotide gated channels, or amino acid permeases) in various *pip2* mutants. Transcript levels of transport-related genes present on the array were not noticeably varied in the mutant plants. Indeed, the expression of these genes was never consistently deregulated more than two-fold in at least two/ three independent biological replica (see Supplementary Table 1). Thus, at least at the transcriptional level the loss-of-function of individual *PIP2* genes did not interfere with these major transport processes.

**Table 8. MIPs expression fold-change in roots of various *pip2* insertional mutants.**

Wild-type and *pip2* mutants were grown hydroponically for 3 weeks and root expression of 35 MIPs genes was analyzed using DNA array. Two biologically independent replicates of twelve mutants and Columbia wild-type were analyzed. The signal intensity of each gene in the mutant plants was compared with the signal intensity of the same gene in the wild-type plants to calculate an expression ratio (mutant *versus* wild-type). In order to avoid a bias caused by T-DNA or transposon insertion, fold-changes (FC) were calculated by averaging expression ratios of the two biologically independent replica of two independent mutants each with the exception of *pip2;4-1* and *pip2;8-1*, for which only one mutant was available. Consequently, only genes consistently deregulated in both mutants were then seen as significant changes. Because specific probes spotted on the array correspond to 3'-UTR, the transcript level of several knockout genes seemed to be similar in the mutant and in the wild-type. However, loss-of-transcript of the respective *PIP2* genes in the *pip2* mutants had been clearly demonstrated by RT-PCR (Results 3.2.2; Fig. 14). Blue labeling indicates genes that were probed twice on the array and asterisks indicate probes designed in our lab. SD: standard deviation.

### 3.4.2 Whole genome transcriptional analysis using Affymetrix ATH1 GeneChip

Our custom-made microarray harbored about 500 gene-specific targets focusing on membrane transporter. Root expression analysis of the single mutants using this custom array did not reveal any transcriptional alteration (Results 3.4.1). Thus, it was reasoned whether a broader analysis could reveal a differentiation of these mutants. In order to extend the *pip2* insertional mutants root transcriptome analysis, the effect of selected mutations on global gene expression was investigated. Genome-wide analyses were carried out using the Affymetrix ATH1 GeneChip, which contains oligonucleotide probesets representing over 25,000 *Arabidopsis* gene sequences. Three single mutants *pip2;1-2*, *pip2;2-3* and *pip2;4-1* were chosen eliminating *PIP2;1*, *PIP2;2* and *PIP2;4*, which represent three of the most abundantly expressed *PIP2* isoforms in roots. Their expression pattern showed strong overlapping for *PIP2;1* and *PIP2;2* in the vasculature and endodermis, while *PIP2;4* was rather restricted to rhizodermis and cortex (see Results 3.1). The selected mutants showed a single T-DNA insertion in the genome and any observed transcriptional changes could therefore be attributed to the corresponding mutated gene. In addition, two double mutants, *pip2;2-3/pip2;1-2* and *pip2;1-2/pip2;4-1* were analyzed. *PIP2;1* and *PIP2;2* represent two of the most highly expressed *PIP2* isoforms in roots and leaves. Leaf water loss experiment (Results 3.3.3.1) indicated a lower decline in leaf water for the double mutants suggesting alteration of leaf water relations. Thus, root and leaf transcriptome of *pip2;2-3/pip2;1-2* was analyzed to investigate whether the combined mutations lead to alteration of root and/ or leaf transcriptome and whether these alterations were different from the single mutants.

Using Affymetrix whole genome array, transcriptional profiles of the selected *pip2* mutants and wild-type plants were analyzed for three independent biological replicas each. The greater than twofold deregulated genes for each mutant were retrieved (Materials and Methods 2.2.9.2) and revealed distinct changes. Different numbers of deregulated genes, 237, 370 and over 1000, were found for *pip2;1-2*, *pip2;2-3* and *pip2;4-1* roots, respectively. For the double mutants, 94 genes were deregulated in roots of *pip2;2-3/pip2;1-2*, whereas 802 were deregulated genes were found for *pip2;1-2/pip2;4-1* corroborating the high number of altered gene transcripts in the *pip2;4* single mutant. The leaf transcriptional profile of the *pip2;2-3/pip2;1-2* double mutant showed 293 deregulated genes. Due to biological as well as technical variations, a higher number of deregulated *per se* would not necessarily mean that one situation is more labile than another one<sup>2</sup>. In order to compare the different mutants and to

---

<sup>2</sup> The data may simply be more homogenous and therefore more genes may pass the filtering conditions.

investigate which genes and processes are most significantly deregulated, the top-hundred deregulated genes retrieved after gene filtering were used (Supplementary Table 2; Method 2.2.9.2).

These top-hundred genes were first assigned to functional categories based on MapMan classification (Thimm et al., 2004) to examine whether *pip2* mutations resulted in significant alterations of any category (Table 9). However, the functional representation of the top-hundred deregulated genes of the mutants was not different compare to that of the expected frequency (Table 9). *Cell wall* and *Miscellaneous* (i.e. various enzyme families) were the only categories exhibiting a statistically significant over-representation in the *pip2;2-3/ pip2;1-2* double mutant (Table 9). In particular, a high enrichment of cell wall-related genes was observed for *pip2;2-3/ pip2;1-2* in roots, but not in leaves (Table 9); 17% of the deregulated genes (i.e. 16 genes) in roots were assigned to this category. Moreover, nearly all these genes (15 genes), mainly related to cell wall synthesis or modification, were down-regulated indicating a significant, coordinated response in this mutant (Table 9 and Supplementary Table 2). Other mutants did not show such a significant enrichment, although *pip2;4-1* and *pip2;1-2/ pip2;4-1* exhibited four down-regulated cell wall-related genes (Table 9 and Supplementary Table 2).

The functional categories *Miscellaneous* showed an enrichment in all mutants, but it was significantly over-represented only in the top-hundred deregulated genes of the *pip2;2-3/ pip2;1-2* leaf transcriptome (Table 9 and Supplementary Table 2). In fact, miscellaneous was found to represent around 10% of the deregulated genes for most mutants and raised to 25% for the *pip2;2-3/ pip2;1-2* leaf transcriptome (Table 9). Within the miscellaneous category, a wide range of enzyme families were found altered such as cytochrome P450, peroxidases, glutathione-S-transferases or enzymes grouped to gluco-, galacto- and mannosidases family or GDSL-motif lipase family (Supplementary Table 2).

It is noteworthy that functional category representation using all deregulated genes was similar to that using top-hundred gene (data not shown).

**Table 9. Classification of deregulated genes obtained by Affymetrix ATH1 expression analyses of *pip2* mutants.**

Top-hundred deregulated genes for the indicated *pip2* single or double mutants were used and classified to determine functional category representation. Assignments into functional categories were taken from MapMan (Thimm et al., 2004). The functional profile was obtained by calculating the percentage of each category in the top hundred deregulated genes. For each category, percentage relative to all genes in the column, the number of assigned genes (in brackets) is indicated. The asterisks denote significance for over-representation based on p-values (two-sided Fisher's Exact test; see Materials and Methods 2.2.9.2): \*\*\* < 10<sup>-5</sup> and \* < 0.002.

The observation that the functional representation of the top-hundred deregulated genes of the mutant was not different compared to that of the expected frequency raised the question whether deregulated genes would also be similar between the different mutants. It was therefore checked whether overlaps could be found between the root transcriptome of the *pip2* mutants, which were displayed by Venn diagrams (Figure 32). The Venn diagram showed a significant overlap between the top-hundred genes of the single mutants. The strongest overlap was observed between *pip2;1-2* and *pip2;2-3* with 41 common deregulated genes,

while *pip2;1-2* and *pip2;4-1* or *pip2;2-3* and *pip2;4-1* exhibited a relatively lower overlap (28 or 15 genes, respectively) (Fig. 32 and Supplementary Table 2). Interestingly, only 11 genes were common to all three single mutants (Fig. 32). These genes were either of unknown function or belonged to the DNA synthesis/chromatin structure/retrotransposon category (Supplementary Table 2). These overlapping genes were exclusively deregulated in the same way (Supplementary Table 2).

When single mutants were compared to double mutants, different results were observed. The double mutant *pip2;1-2/ pip2;4-1* showed significant overlap with the corresponding single mutants, i.e. 27 and 49 genes for *pip2;1-2* and *pip2;4-1*, respectively (Fig. 32). There were even 18 genes in common with the *pip2;2-3* mutant (Fig. 32). In fact, it is noteworthy that nine of the 11 genes common to all single mutants were also deregulated in the *pip2;1-2/ pip2;4-1* double mutant (Fig. 32; Supplementary Table 2). On the other hand, *pip2;2-3/ pip2;1-2* showed a different result, because only few deregulated genes were overlapping with the other mutants. Only 5, 6, 5 and 3 common deregulated genes with *pip2;1-2*, *pip2;2-3*, *pip2;4-1* and *pip2;1-2/ pip2;4-1*, respectively were found. In fact, only one gene, a lipid transfer protein gene LTP5 (At3g51600) was deregulated in the *pip2;2-3/ pip2;1-2* double mutant root transcriptome as well as in all single mutants. However, it was up-regulated in the double mutant, whereas it was down-regulated in the single mutants (Supplementary Table 2).

**Figure 32. Venn diagram of genes deregulated in various *pip2* knockout mutants.**

The numbers are based on the top-hundred deregulated genes for three single mutants and *pip2;1-4/ pip2;4-3* double mutant (see above; Method 2.2.9.2).

Eventually, there were three genes common to both double mutants. These genes were specific to double mutants and were deregulated in the same way. Two of them were genes of unknown function and one belonged to the proton-dependent oligopeptide transport family protein (Supplementary Table 2).

Thus, these analyses showed that deregulated genes were for the most part specific to a particular mutant indicating a different transcriptional response of each *pip2* mutant tested. Nevertheless, genes were mostly of unknown functions or involved in RNA or protein metabolism and thus did not give clear hints for the function of a PIP2 particular isoform (Supplementary Table 2).

The comparison of the leaf and root transcriptome of *pip2;2-3/pip2;1-2* double mutant led to a similar conclusion. Based on the sole gene categories, several differences were observed. As mentioned above, cell wall and miscellaneous categories were particularly over-represented ( $p\text{-value} < 10^{-5}$ ) in the top-hundred deregulated genes of roots and leaves, respectively (Table 9; Supplementary Table 2). In addition, six genes classified into development (e.g. senescence) were found to be deregulated in leaves, whereas no genes were found in roots (Supplementary Table 2). Other categories exhibited the expected frequency (see above; Table 9). When considering the individual genes that had been altered (Supplementary Table 2), only three differentially expressed genes were found in both roots and leaves; an iron superoxide dismutase (FSD1) and an acyl CoA reductase were downregulated, while an unknown protein was strongly upregulated. The latter was also upregulated in the *pip2;1-2* single mutant. In conclusion, these data suggested that *pip2* double mutation triggered a differential response in roots than in leaves.

### **3.5 *PIP2s* co-expression and stress responsiveness analyses using publicly available microarray data**

The use of microarray in *Arabidopsis thaliana* has increased considerably in the past few years. They now represent an enormous volume of data that are made available on public databases, such as the Nottingham *Arabidopsis* Stock Center (NASC) (Craigon et al., 2004), The *Arabidopsis* Information Resource (TAIR) (Rhee et al., 2003) or the Gene Expression Omnibus (GEO) at the National Center for Biotechnology Information (Edgar et al., 2002). In addition, many web-based tools have been developed to assist the interpretation of these large microarray gene expression databases. One aim of microarray studies is to understand how genes are regulated and to integrate those regulations in biological processes. Here, the

primary goal was to extract information from existing microarray data using several web-based tools. The *Arabidopsis* Co-expression Tool (ACT) and the Bio-Array Resource (BAR) were used in order to find genes co-regulated with *PIP2* genes in a general manner or in specific contexts and, hence, to infer biological processes in which *PIP2* genes might be involved and that could lead to hypothesis on their biological functions. Furthermore, the Genevestigator Meta-Analyzer tool was used to extract the transcription profile of *PIP2* genes in a broad range of stress conditions to investigate whether *PIP2* genes can be distinguished based on their differential stress responsiveness.

### **3.5.1 Co-expression analyses revealed transcriptional interrelation of *PIP2* genes with *MIP* members and other processes.**

Microarray data contain information on the coordinated expression level of nearly all genes in the analyzed condition. Gene co-expression analyses can identify genes involved in correlated processes based on their co-regulation and paralleled expression patterns across many different situations and experimental conditions. Web-based tools such as the Bio-Array Resource (Toufighi et al., 2005), CSB.DB (Steinhauser et al., 2004) and the *Arabidopsis* Co-expression Tool (Jen et al., 2006; Manfield et al., 2006) are allowing gene co-expression analyses based on *Arabidopsis* microarray data. In previous studies, co-expression tools have been used to search for genes involved in determined biological processes (Lisso et al., 2005; Persson et al., 2005; Rautengarten et al., 2005). Here, individual *PIP2* genes were used as a starting point to find information about correlated physiological pathways. Two different approaches were performed. First, the ACT was used to do co-expression analyses on mixed experiments encompassing a wide range of conditions (e.g. different tissues, growth conditions or ecotypes). Second, specific analyses using selected datasets, e.g. roots, leaves, abiotic or biotic stresses, were done using the Bio-Array resource.

Co-expression analyses on the *Arabidopsis* Co-expression Tool (ACT) are based on *Arabidopsis thaliana* data from 322 ATH1 microarray studies, which were all processed at NASC. Hence, this data set is more homogeneous in technical terms than other compilations and as a consequence the array results are more suited for comparison. On the other hand, these data also cover a wide range of biological processes and conditions. Positively and negatively co-regulated genes across a wide range of microarray experiments might reveal robust generalities toward a better understanding of *PIP2* functions.

To visualize the extent and significance of correlation between two genes with different Pearson correlation factors (r-value), two examples were chosen. The data for two genes

displaying all 322 experiments encompassed within the ACT were plotted. A Pearson correlation coefficient of 0.6 / -0.6 was chosen as a threshold for both positively and negatively correlated genes. Indeed, an r-value above 0.6 still gives a reasonable co-expression as shown in the scatter plots, whereas a value just below 0.6 results in a clearly more undirected, centered plot (Fig. 33).

**Figure 33. Co-correlation scatter plot of pairs of genes with different r-values.**

The scatter plots show the expression values for 322 experiments included in the ACT for two genes with a Pearson correlation coefficient of 0.632 (a) or 0.581 (b). As an example *PIP2;2/PIP2;3* against *PIP2;4* (a) and *PIP2;1* against *PIP2;2/PIP2;3* (b) were chosen.

This experimental cut-off threshold ( $r\text{-value} \geq 0.6$ ) was also used for co-expression analyses based on other co-expression tools (e.g. BAR), since all web-based tools offer the Pearson correlation coefficient for statistical analyses, which was consistently selected here.

At last, it has to be noted that all the web-based tools based on Affymetrix whole genome arrays (ATH1) exhibit some non-specific probesets that cross-hybridize with other sequences. As indicated previously, *PIP2;2* and *PIP2;3* as well as *PIP2;7* and *PIP2;8* hybridize to the same probesets on the ATH1 array, respectively and therefore cannot be differentiated. Since *PIP2;2* and *PIP2;3* have been implicated with different functions (see above; also Javot et al., 2003), their combined expression could be problematic; however, most probably their expression values are dominated by the more highly expressed *PIP2;2*.

Each *PIP2* gene was submitted to a co-expression analysis using the ACT tool (Jen et al., 2006; Manfield et al., 2006), where Affymetrix ATH1 expression analyses encompassing a wide range of more than 300 conditions, but collectively hybridized at NASC can be approached. Both the positively ( $r\text{-value} \geq 0.6$ ) and negatively ( $r\text{-value} \leq -0.6$ ) co-regulated genes for each *PIP2* were then submitted to MapMan, another web-based tool that allows the

classification of genes into functional categories (Thimm et al., 2004) (Method 2.2.10; Table 11). Additional co-expression analyses were also performed using thematic datasets at Bio-Array Resource (BAR; Toufighi et al., 2005) primarily from AtGenExpress experiments ([www.arabidopsis.org/info/expression/ATGenExpress.jsp](http://www.arabidopsis.org/info/expression/ATGenExpress.jsp); Kilian et al., 2007) to check the robustness of the enriched functional categories or to identify biological processes, which might involve *PIP2* genes in a specific context. In most cases, the conclusions based on mixed experiments from NASC (Table 10 and Supplementary Table 3) were validated when using distinct datasets generated from AtGenExpress such as hormone treatments, abiotic or biotic stresses (Supplementary Tables 4 to 8; see below).

Interestingly, the analysis of the broad ACT collection did not reveal genes showing significantly anti-correlated patterns with a *PIP2* gene; similarly, only a few negatively co-expressed genes were retrieved at BAR using several AtGenExpress datasets (see below; Supplementary Tables 4 to 8). However, different numbers of positively co-regulated genes were found. About 50 to 100 genes were co-expressed with *PIP2;1*, *PIP2;2/2;3*, *PIP2;5* and *PIP2;7/2;8*, whereas considerably more were found for *PIP2;4* and *PIP2;6* (Supplementary Table 3). With the exception of *PIP2;5* their classification according to MapMan revealed significantly enriched functional categories ( $p < 0.002$ ), which clearly differed among the *PIP2* members (Table 10).

It should be noted that some gene categories were never or little represented in any of *PIP2* co-expression lists, e.g. CHO metabolism, C, S, N metabolism, amino acid metabolism, metal handling, mitochondrial electron transport and ATP synthesis, and nucleotide metabolism. This observation may indicate processes, which are not related to or not influenced by *PIP2* members.

Surprisingly, *PIP2;1* and *PIP2;6* showed a strong correlation with photosynthesis-related genes (10% and 17% of co-expressed genes, respectively). In addition, other gene categories related to photosynthesis such as tetrapyrrole synthesis or redox regulation were also significantly over-represented among *PIP2;6* co-expressed genes (Table 10).

**Table 10. Functional categories assignment of *PIP2* correlated genes.**

*PIP2* correlated genes exhibiting a significant Pearson correlation coefficient were retrieved using the *Arabidopsis* Co-expression Tool and assigned to functional categories according to MapMan (Thimm et al., 2004) (see Materials and Methods). For each category, percentage relative to all genes in the column, the number of assigned genes (in brackets) is indicated. The asterisks denote different levels of significance based on p-values (two-sided Fisher's Exact test; Experimental Procedures): \*\*\* <math>10^{-10}</math>, \*\* <math>10^{-5}</math>, and \* <math>0.002</math>.

*PIP2;6* is mostly detected in leaves and therefore co-regulation with other genes primarily expressed in leaves could be accidental. Therefore, to re-assess the correlation to photosynthesis, specific datasets based on leaf material only provided at BAR were used ([www.arabidopsis.org/info/expression/ATGenExpress.jsp](http://www.arabidopsis.org/info/expression/ATGenExpress.jsp)). However, when selecting expression analyses comprising biotic stresses applied to leaves both *PIP2;1* and *PIP2;6* co-

regulated genes were again significantly enriched with photosynthesis-related genes (p-values  $5 \cdot 10^{-40}$  to  $6 \cdot 10^{-58}$ ; Supplementary Tables 4 and 7). The *PIP2;6* co-regulated genes derived from the biotic stress response set revealed another strong association. Among the top twenty correlated genes with Pearson coefficients of 0.737 to 0.812 eight genes were related to cell wall biosynthesis, such as cellulose synthase genes *CESA1*, 2, 3, 5 and 6 as well as *COBRA* involved in anisotropic elongation (Table 11). Furthermore, stress category was significantly enriched with *PIP2;6* as well in the shoot abiotic stress dataset; the same was only observed for *PIP2;2/2;3* among all *PIP2* genes (Supplementary Tables 5 and 7).

**Table 11. Twenty most highly co-expressed genes with *PIP2;6* among a dataset (AtGenExpress biotic stress dataset) covering pathogen responses in shoot.**

Genes related to cell wall metabolism are clearly enriched.

Among NASC experiments a high number of genes encoding enzymes involved in oxidative stress response and secondary metabolism including peroxidases (13), glutathione-S-transferases (2), cytochrome P450 monooxygenases (16) and UDP-glycosyl transferases (8) were correlated with *PIP2;4*, which were listed by MapMan in part among the miscellaneous category (Table 10; Supplementary Table 3). A significant over-representation of stress category was also found among NASC experiments and among the thematic datasets for root abiotic stress responses (Table 10; Supplementary Tables 3 and 6).

Eventually, among NASC experiments *PIP2*;7/2;8 exhibited significant over-representation of the cell wall and miscellaneous categories, where additional genes potentially related to cell wall metabolism such  $\beta$ -glucanases were assigned (Table 10; Supplementary Table 3). However, this correlation was not substantiated by analyses of abiotic, biotic, or hormone datasets from AtGenExpress. Instead, various over-representations of categories were found among different AtGenExpress datasets (Supplementary Table 8).

In addition to the differential co-regulation of *PIP2* genes with functional classes, the individual co-regulated genes were also different in most cases. However, there were a few notable exceptions (Fig. 34). The most striking instance is the overlap between *PIP2*;2/2;3 and *PIP2*;4; two third out of 58 *PIP2*;2/2;3 co-regulated genes were also co-regulated with *PIP2*;4 (Fig. 34). Among many genes without a documented function a high affinity phosphate transporter *PHT1*, the peroxidase *RCI3* involved in cold and salt tolerance as well as - exclusively among *PIP2*s - two  $\delta$ -*TIP* members *TIP2*;2 and *TIP2*;3 were co-regulated with both *PIP2* genes (Supplementary Table 3).

**Figure 34. Venn diagram showing overlap for the positively correlated genes with the individual *PIP2*.**

In the left diagram, an actin 8 gene was found to be common to *PIP2*;1, *PIP2*;2/*PIP2*;3 and *PIP2*;4, whereas a *PIP1*;2 gene was found to be common to *PIP2*;1, *PIP2*;2/*PIP2*;3 and *PIP2*;7/*PIP2*;8 (right diagram).

Furthermore, without taking into account the co-regulation among *PIP* or *TIP* genes (see below), only *PIP2*;1 exhibited an considerable overlap with *PIP2*;6 and *PIP2*;7/2;8 (Fig. 34; Supplementary Table 3). Eventually, only two cases were found within the NASC data that revealed common co-regulated genes among more than two *PIP2* genes. Actin 8 (At1g49240) was associated with *PIP2*;1, *PIP2*;2/2;3 as well as *PIP2*;4, whereas *PIP1*;2 and a highly and ubiquitously expressed acid phosphatase (At5g44020) of unknown function were co-expressed with *PIP2*;1, *PIP2*;2/2;3, and *PIP2*;7/2;8 (Fig. 34; Supplementary Table 3).

Surprisingly, a significant enrichment of transport-related genes was only detected among genes co-expressed with *PIP2;1* and *PIP2;2/2;3*, yet these were dominated by other *PIP* and *TIP* genes (Table 10; Supplementary Table 3). Four of the five *PIP1* genes (*PIP1;1*, *PIP1;2*, *PIP1;3*, *PIP1;5*) and three *TIP* genes (*TIP1;1*, *TIP1;2* and *TIP2;1*) were co-expressed with *PIP2;1*, while two *PIP1* genes (*PIP1;1*, *PIP1;2*), *PIP2;4*, and three *TIP* genes (*TIP1;1*, *TIP2;2*, *TIP2;3*) were correlated with *PIP2;2/2;3* (Table 12). Among other *PIP2* genes only *PIP2;4* and *PIP2;7/2;8* did show a correlation with other *PIP* and *TIP* as well, whereas *PIP2;5* and *PIP2;6* clearly did not, indicating a specific role among *PIP* members (Tables 12; Supplementary Table 3). In fact, *PIP2* genes showed a much better correlations with *PIP1* genes than with other *PIP2* members indicated by considerably high *PIP2-PIP1* correlation coefficients for the couples *PIP2;1* vs. *PIP1;2*, *PIP2;2/2;3* vs. *PIP1;1*, or *PIP2;7/2;8* vs. *PIP1;3* ( $r > 0.82$ ; Table 12). This observation may provide an independent hint towards a functional cooperation between *PIP1* and *PIP2* members.

**Table 12. Correlation of *PIP2* members with *PIP* and *TIP* genes according to ACT co-expression analyses.** Co-expression analyses were performed on the basis of 322 ATH1 microarray data at ACT (Manfield et al., 2006). For each *PIP2* gene, the Pearson correlation coefficients with other *PIP1* or *PIP2* as well as *TIP* members are indicated. All other *MIP* genes did not show correlations  $> 0.6$ . <sup>1</sup>The Affymetrix probeset for *TIP2;1* also hybridizes to At3g16250, which encodes a ferredoxin-related protein.

### 3.5.2 Principal component analysis of *PIP2* transcriptional responses to various stimuli revealed differential reactions.

Public microarray databases can also be used to determine how genes of interest are expressed during specific growth stages or are responding to different conditions. Geneinvestigator (Zimmermann et al., 2004; Zimmermann et al., 2005) is a very valuable tool for analyzing such public microarray data. Previously, the Geneinvestigator Meta-Analyzer tool has been used to study *PIP* expression profile in various anatomical structures (Results 3.1.2). Here, the Meta-Analyzer tool (Version 3; Zimmermann et al., 2005) was used to examine the transcriptional changes of *PIP* genes in response to diverse abiotic and biotic stresses as well as to chemical and hormone treatments in order to identify differential reactions and functional involvements of *PIP* genes.

Expression ratios of *PIP2* genes in response to various treatments with respect to control experiments were extracted using the Geneinvestigator Meta-Analyzer tool (Method 2.2.11). In order to focus on typical conditions in which water channel regulation is supposed to occur, several atypical treatments were neglected (i.e. genotoxic stress (abiotic stress), cycloheximide, MG13 and PNO8 treatments (chemical treatments). Finally, expression ratios of *PIP2* genes in 54 conditions were retained (Methods 2.2.11; Supplementary Table 9 for *PIP2* genes expression ratio and list of all treatments). The selected conditions included 54 different data sets that had been obtained by the AtGenExpress consortium using *A. thaliana* Col-0 and a common Affymetrix ATH1 array platform (Kilian et al., 2007; [www.arabidopsis.org/info/expression/ATGenExpress.jsp](http://www.arabidopsis.org/info/expression/ATGenExpress.jsp); Supplementary Table 9), which limits variability due to biological and technical differences. To identify similar and/or differential patterns among the transcriptional responses of *PIP* to the various conditions, the data were subjected to a principal component analysis (PCA; see Methods 2.2.11; Fig. 35).

The PCA defined distinct transcriptional responses of *PIP2* genes and only *PIP2;1* and *PIP2;7/2;8* exhibited an overlapping profile (Fig. 35a). The group formed by *PIP2;1* and *PIP2;7/2;8* showed a completely opposite response in comparison to *PIP2;4*, which was almost exclusively described by component 1. Component 1 was dominated by *Pseudomonas* infection and AgNO<sub>3</sub> treatment as the most discriminating variables. These two groups were independent from the responses of *PIP2;2/2;3*, *PIP2;5* and *PIP2;6*, which were also dependent on component 2. Yet, *PIP2;2/2;3* showed a roughly opposite responsiveness from *PIP2;5* and *PIP2;6* (Fig. 35a). Several different conditions that potentially affect plant water relation such as heat, cold stress, osmotic or salt stress contributed most to this distinction.

**Figure 35. Principal component analyses of *PIP* transcriptional responses to diverse stimuli.**

PCA were based on a large Affymetrix microarray dataset produced by the AtGenExpress consortium and extracted at Genevestigator using the Meta-Analyzer tool (Zimmermann et al., 2005). *PIP* expression ratios of 54 stress conditions and treatments were retrieved (Kilian et al., 2007; Method 2.2.11; Supplementary Table 9). PCA were performed using  $\log_2$ -transformed expression ratios and row-centered data (Method 2.2.11) for (a) *PIP2* genes and (b) *PIP2* + *PIP1* genes. The total variance covered by the two components is 70% (a) and 62% (b). A radius of  $r > 3$  was arbitrarily chosen from the polar coordinates to extract treatments most significantly contributing to the differentiation. The conditions that mostly influenced the PCA were: 1 heat stress in roots, 2 *Pseudomonas syringae* infection, 3 osmotic stress in green tissue (late/ 24 h), 4 salt stress in green tissue (Late/ 24 h), 5 cold stress in green tissue (late / 24 h), 6 cold stress in roots (late, 24 h), 7 TIBA, 8 AgNO<sub>3</sub>, 9 osmotic stress in roots (late/ 24 h), 10 salt stress in salt in roots (late/ 24 h), 11 *Botrytis cinerea* infection.

In terms of *PIP2* transcriptional reactions to individual cues, it is noteworthy that *PIP2;2/2;3*, *PIP2;4* and *PIP2;5* were more frequently deregulated than other *PIP2* genes (Supplementary Table 9). In particular, *PIP2;4* was often downregulated in all categories. *PIP2;5* was upregulated by several abiotic stresses and *Pseudomonas* infection, but rarely responsive to other conditions. *PIP2;2/2;3* also responded to several abiotic stresses, but showed both down- and upregulation. *PIP2;5* and *PIP2;6* were strongly upregulated by cold stress in both roots and leaves, while other genes did not respond or were affected in an opposite way (*PIP2;2/2;3*) (Supplementary Table 9).

Differential responses were also observed for *PIP2* genes upon salt stress in roots or green tissues. *PIP2;5* exhibited significant upregulation upon salt stress in green tissues. In contrast, all *PIP2* genes at least tended to be downregulated upon salt stress in roots. The gene-specific responses were also observed for drought, osmotic and heat treatments. Only *PIP2;2/2;3*, exhibited a significant upregulation in green tissue upon drought, whereas *PIP2;5* was induced in roots. Similarly, these two genes, in particular *PIP2;2/2;3*, were upregulated in green tissue upon heat stress. Finally, *PIP2;2/2;3*, *PIP2;4*, and *PIP2;7/2;8* were suppressed by osmotic stress, yet at different time points or in distinct organs (Supplementary Table 9).

*PIP2* genes were only rarely deregulated upon exogenous application of plant hormones or chemicals interfering with hormone action. However, there was a noticeable suppression of *PIP2;4* by IAA and auxin (transport) inhibitors; only *PIP2;2/2;3* showed a similar tendency. Furthermore, *PIP2;1*, *PIP2;2/2;3*, and again *PIP2;4* were downregulated by salicylic acid and the ethylene inhibitor AgNO<sub>3</sub> (Supplementary Table 9).

Eventually, *PIP2* genes could also be differentiated by their responsiveness to biotic stresses. Infection by the avirulent pathogen *Pseudomonas syringae* pv. *tomato* DC3000 specifically triggered a strong upregulation of *PIP2;5*. In contrast, inoculations with fungi *Phytophthora infestans* or *Botrytis cinerea* downregulated *PIP2;5* and *PIP2;6* or *PIP2;4* and *PIP2;7/2;8*, respectively (Supplementary Table 9).

Recent publications demonstrated that *PIP1* and *PIP2* proteins might interact and synergistically enhanced water permeability when heterologously expressed (Fetter et al., 2004; Zelazny et al., 2007). In addition, certain *Arabidopsis PIP1* and *PIP2* genes are co-transcribed in many instances (see above). Therefore, it was interesting to extend the PCA analysis and include both *PIP1* and *PIP2* genes, which revealed several associations among *PIP1* and *PIP2* (Fig. 35b). *PIP2* gene responses were described by the first two components of this combined PCA similarly to the PCA using only *PIP2* genes, although some of the

most discriminating variables had changed and included responses to salt and osmotic stress as well as *Botrytis cinerea* infection (Fig. 35a and b). *PIP2;2/2;3* and *PIP2;4* were now grouped together and associated with *PIP1;1*. This association was dependent *e.g.* on a similar downregulation after *Pseudomonas syringae* infection or upon salt or osmotic stress in roots. A rather opposite response was exhibited by a group represented by *PIP2;1*, *PIP2;7/2;8*, and *PIP1;3* as well as by *PIP1;2* (Fig. 35b). They were in part characterized by their common downregulation upon osmotic stress or *B. cinerea* infection (Fig. 35b; Supplementary Table 9). A third group associated *PIP2;6* and *PIP1;4*. In contrast, *PIP2;5* and *PIP1;5* defined two distinct responses showing opposite reactions almost completely (*PIP1;5*) or partially (*PIP2;5*) independent from all other groups (Fig. 35b; Supplementary Table 9). This may suggest specific functions of these two genes. Besides *PIP1-PIP2* associations, it is important to emphasize that *PIP1* transcriptional reactions were also distinct from each other (Fig. 35b). Thus, these results do support the notion that *PIP2* as well as *PIP1* members may have evolved differential responsiveness and, consequently, gene-specific, non-redundant functions related to distinct stresses.

### 3.6 Interaction between PIP2 and PIP1 isoforms

Recent publications demonstrated interaction between maize *ZmPIP2* and *ZmPIP1* members at the protein level (Fetter et al., 2004; Zelazny et al., 2007). In oocytes, PIP1 members do not increase or do increase water permeability in a considerably weaker way in contrast to PIP2 members. However, co-expression of both PIP1 and PIP2 in *Xenopus* oocytes resulted in an increase in water permeability that was dependent on the amount of injected PIP1 (Fetter et al., 2004; Temmei et al., 2005). Using FRET/Fluorescence lifetime imaging microscopy in living maize cells Zelazny et al. (2007) demonstrated a PIP2-PIP1 heteromerization which regulated PIP1 subcellular localization. Interaction between PIPs is not restricted to maize since *Mimosa pudica* *MpPIP2;1* and *MpPIP1;1* were also shown to increase water permeability of the oocyte membrane and to interact in COS7 cells when co-expressed (Temmei et al., 2005).

It was then suggested that PIP2-PIP1 heteromerization could be a mean for PIPs to regulate their activity (Chaumont et al., 2005; Zelazny et al., 2007).

Fetter et al. (2004) demonstrated the importance of loop E in the interaction process although the influence should be indirect based on the MIP 3D-structure. By comparing the structural model of *ZmPIP1;1* and *ZmPIP1;2* and performing molecular dynamics simulation, it was suggested that the loop E residues affect the structure of the pore and possibly its channel activity (Chaumont et al., 2005). Thus, the amino acid sequence of the important region of loop E was compared in order to examine whether *Arabidopsis* PIPs harbor amino acids that had been suggested to be important for this type of isoform interactions (Fig. 36). Fetter et al. (2004) demonstrated the importance of four amino acids (amino acids in position 247, 251, 252 and 256 in Figure 36). However, in their experiment, Fetter et al. replaced the four amino acids altogether, therefore, it cannot be excluded that some of these amino acids do not account for the multimerization. Hence, with regard to these amino acids, heteromerization of PIP1 and PIP2 could also occur in *Arabidopsis* (Fig. 36). The position 247 is completely conserved among the PIP1 and PIP2 interacting members (Fig. 36). *ZmPIP1;2* and *MpPIP1;1*, which have been shown to interact with PIP2 have an isoleucine (I) in position 247. In contrast, it is a valine (V) for PIP2 or *ZmPIP1;1*. In this position, all *AtPIP1* have an I, whereas it is a V for all *AtPIP2* members except *AtPIP2;5*.

Arginine251 of *ZmPIP1;2* is replaced by a lysine (K) in all the *AtPIP1*, which is usually considered a conservative exchange of basic side chains, although exact sizes and potential interactions may be different. Moreover, *MpPIP1;1* that was shown to interact with *MpPIP2;1* also has a K, indicating that the replacement of the R by a K should not abolish the interaction

*per se*. Similarly, at this position, members that do interact have different amino acid suggesting that the interaction is independent of the amino acid residue at position 251 (Fig. 36).

**Figure 36. Sequence comparison of loop E of *ZmPIP* and *AtPIP*.**

The important amino acids are underlaid in yellow. *ZmPIP1*;1 did not show interaction unless loop E was replaced with *ZmPIP1*;2 loop E (amino acids 247 to 256) meaning that the amino acids 247, 251, 252 and 256 are probably involved in the interaction or recognition of the proteins. The numbering is referring to *ZmPIP1*;2, whereas other sequences are only aligned and actually numbering might slightly differ.

At position 252, both D and H may be in agreement with an interaction, since both *ZmPIP1*;2 and *MpPIP1*;1 were shown to enhance water permeability. Nevertheless, all *AtPIP1* (and *AtPIP2*;5) present a D at this position similarly as *ZmPIP1*;2. For PIP2 members shown to interact, amino acid D252 for *ZmPIP2* or a S252 for *MpPIP2*;1 was found. The same amino acids are present in *AtPIP2*;1, *AtPIP2*;2, *AtPIP2*;3, and *AtPIP2*;5 (Fig. 36).

A major difference of the interacting *ZmPIP1*;1 and *AtPIP1* members is the replacement of neutral asparagine N256 by an acidic aspartate D (Fig. 36). In addition, *MpPIP1*;1 also possesses a charged, yet basic amino acid, H, at this position (Fig. 36).

Based on this amino acid sequences alignment, all *AtPIP1* and *AtPIP2* might be candidates for heteromerization. *AtPIP2*;3 was also shown to have an effect on water permeability when co-expressed with *ZmPIP1*;2 (Fetter et al., 2004). Thus, *AtPIP2*;1 and *AtPIP2*;2 are good candidates, since they are highly similar to *AtPIP2*;3. Interestingly, *AtPIP2*;5 is very similar to *ZmPIP1*;2 or *MpPIP1*;1 and, hence is likely to act in a manner similar to them.

### 3.6.1 Specificity of antisera against *AtPIP1* and *AtPIP2*

To detect and analyze PIP protein expression polyclonal anti-*AtPIP1*;1 and anti-*AtPIP2*;2 antisera had been raised in our laboratory against the 42 N-terminal amino acids of *AtPIP1*;1 and 17 C-terminal amino acids of *AtPIP2*;2. According to the high amino acid sequence homology of the different members, the antisera should react with other isoforms (Fig. 37). Sequence alignment suggests that anti-*AtPIP1*;1 antiserum should react with all *AtPIP1* isoforms. Only *AtPIP1*;5 is somewhat more divergent, since three amino acids in a row are different in the central part (amino acids 27 to 29; Fig. 37).

Figure 37. Sequence alignment of *AtPIP1* and *AtPIP2* with the corresponding epitope used to raise anti-*PIP1*;1 or anti-*PIP2*;2 antisera.

*AtPIP2*;1, *AtPIP2*;2 and *AtPIP2*;3 are absolutely identical in the epitope region and therefore collectively recognized by the antiserum, while other *AtPIP2* members are relatively different (Fig. 37).

To confirm experimentally with which PIP members the antisera would react, the N-terminal region of *AtPIP1*;5 and the C-terminal region of *AtPIP2*;4, *AtPIP2*;5, *AtPIP2*;6, *AtPIP2*;7 and *AtPIP2*;8 were amplified from genomic DNA by PCR and cloned via GATEWAY technology into the vector pDEST15, which allows the expression of recombinant fusion protein with glutathione-S-transferase (GST) in *E. coli* (Method 2.2.4.6). All fragments had been verified by DNA sequencing. The affinity-purified proteins were checked by SDS-PAGE and staining

with Coomassie brilliant blue (Fig. 38). A reference GST fusion protein carrying an extension of 23 amino acids due to flanking vector sequences was used as a control (Fig. 38, lane 1).

**Figure 38. Identification of GST-PIP fusion proteins.**

5  $\mu$ g of GST reference protein (lane 1, MW 29.53 kDa), 10  $\mu$ g of fusion protein GST-PIP1;1 (lane 2), GST-PIP1;5 (lane 3), 5  $\mu$ g of fusion protein GST-PIP2;2 (lane 4), GST-PIP2;4 (lane 5), GST-PIP2;5 (lane 6), GST-PIP2;6 (lane 7), GST-PIP2;7 (lane 8) and GST-PIP2;8 (lane 9) were loaded on a 12% SDS-PAGE and stained with Coomassie brilliant blue.

In a Western blot analysis the rabbit anti-*At*PIP1;1 antiserum indeed reacted with *At*PIP1;1 as well as with the more divergent *At*PIP1;5 fusion protein indicating the collective detection of all *At*PIP1 members (Fig. 39a). Since GST-PIP1;1 protein were used to raised the anti-PIP1;1 antiserum, it was pre-incubated with 10 $\mu$ g/mL GST protein for 1 hour to compete for the GST-directed antibodies prior to incubation with membrane. Nevertheless, the reactivity towards GST was not completely abolished (Fig. 39a, lane 1). However, signal with GST-PIP1;5 was much stronger indicating that the anti-PIP1;1 antiserum also recognized PIP1;5. In case of anti-PIP2;2 antiserum, a synthetic peptide coupled to keyhole limpet hemocyanin was used to raise the antibody and therefore GST protein could not interfere. However, the anti-PIP2;2 antiserum was treated similarly as anti-PIP1;1 antiserum. The GST-PIP2;2 fusion protein was used as a positive control to check the specificity of a rabbit anti-PIP2;2 antiserum against the other *At*PIP2 members except the identical *At*PIP2;1 and *At*PIP2;3. However, only *At*PIP2;2 was detected and neither *At*PIP2;4, *At*PIP2;5, *At*PIP2;6, *At*PIP2;7, or *At*PIP2;8 was recognized by the antiserum (Fig. 39b).

**Figure 39. Specificity of anti-PIP1;1 and anti-PIP2;2 antisera.**

GST-PIP fusion proteins were extracted and separated on a 12% SDS-PAG and blotted onto PVDF membrane. The membrane was incubated with rabbit (a) anti-PIP1;1 antiserum and (b) anti-PIP2;2 antiserum. Bound primary antibodies were detected with anti-rabbit-cy5-linked secondary antibodies and scanning with Fuji FLA3000 image reader. M: Protein Marker (kDa); (a) lane 1: 10 ng GST protein; lane 2: 10 ng GST-PIP1;1 protein and lane 3: 10 ng GST-PIP1;5 protein. (b) Lane 1 to 6: 10 ng GST-PIP2;4, -2;5, -2;6, -2;7, -2;8 and -2;2 protein. It should be noted that for GST-PIP protein, concentrations were adjusted to account for degradation observed previously (Fig. 38). Thus, a similar amount of protein was loaded by adjusting concentrations of each GST-PIP relative to the GST protein alone (set as 1).

Competition experiments with PIP-GST fusion proteins were also carried out to ensure the specificity against PIP1 or PIP2 proteins also in plant membrane preparations (Fig. 40). Microsomal fractions from *Arabidopsis* roots were prepared, separated on a SDS-PAG and probed using the antisera. The band could be competed by pre-incubation of antiserum with fusion protein GST-PIP1;1 or GST-PIP2;2 (Fig. 40).

**Figure 40. Anti-PIP1;1 and anti-PIP2;2 antisera specifically recognized PIP proteins.**

Microsomal fractions from roots of 3-week-old *Arabidopsis* plants grown hydroponically were extracted, separated on a 12% SDS-PAG and blotted onto PVDF membrane. The membrane was incubated with: lane 1: rabbit anti-PIP2;2 antiserum; lane 2: rabbit anti-PIP2;2 antiserum and 10  $\mu\text{g}/\mu\text{l}$  GST-PIP2;2 protein; lane 3: rabbit anti-PIP1;1 antiserum with 10  $\mu\text{g}/\mu\text{l}$  GST-PIP1;1 protein and lane 4: rabbit anti-PIP1;1 antiserum. Bound primary antibodies were detected with anti-rabbit-cy5-linked secondary antibodies and scanning with Fuji FLA3000 image reader. M: Protein Marker (kDa).

### 3.3.1 Expression of PIP2 and PIP1 proteins in *pip2* knockout mutants

PIP1-PIP2 heteromerization has been demonstrated by transient co-expression or co-purification of PIP1 and PIP2 proteins (Fetter et al., 2004; Temmei et al., 2005). Data mining

of publicly available *Arabidopsis* microarray expression data revealed a high correlation at the transcriptional level between certain *PIP1* and *PIP2* members, such as *PIP1;2* and *PIP2;1*, *PIP1;1* and *PIP2;2/2;3* as well as with *PIP1;3* and *PIP2;7/2;8* (see Table 12, Results 3.5). Here, the *pip2* knock-out collection offered a different approach towards a PIP1-PIP2 interrelation by asking whether the complete loss of an individual PIP2 protein has an influence on PIP1 protein levels.

Microsomal fractions from roots and leaves of three week-old, hydroponically grown *Arabidopsis* plants were then monitored. Protein amount was measured according to the Esen test from denatured samples (Esen, 1978); equal amount of microsomal fraction was then separated by SDS-PAGE, blotted onto PVDF membrane and PIP expression was analyzed and quantified using ImageJ (version 1.37v; <http://rsb.info.nih.gov/ij/>) (Fig. 41). PIP protein expression was monitored collectively for *AtPIP1* isoforms using the anti-*AtPIP1;1* antiserum and for *AtPIP2;1*, *AtPIP2;2* as well as *AtPIP2;3* using the anti-PIP2;2 antiserum. Hence, only changes in the expression of these proteins would be detectable.

As expected, a reduction of about 40% in the expression of PIP2 protein was observed in *pip2;1* and *pip2;2* knock-out mutants in roots (Fig. 41a and b). In the other *pip2* mutants, no significant changes of PIP2 protein level were measured indicating that PIP2;1, PIP2;2 and/ or PIP2;3 were not significantly influenced in these mutants (Fig. 41). Interestingly, *pip2;1* and *pip2;2* mutants showed a concomitant reduction of PIP1 proteins by 20 to 30%, whereas other *pip2* knockouts had no significant effect on PIP1 amounts (Fig. 41).

Two double mutants were tested and confirmed the results of single mutants (Fig. 41). Indeed, *pip2;2-3/ pip2;1-2* showed an additive phenotype and a barely detectable PIP2 signal in roots, while *pip2;1-2/ pip2;4-1* showed a reduction similar to that of *pip2;1-2* alone (Fig. 41). In those mutants, PIP1 expression level was also slightly reduced (Fig. 41). The *pip2;1-2/ pip2;4-1* double mutant showed a reduction similar to that of *pip2;1* single mutants (about 30%) while *pip2;2-3/ pip2;1-2* showed a more pronounced reduction (about 50%; Fig. 41).

PIP expression of two *pip1* knockout mutants, *pip1;1-1* and *pip1;2-1*, were analyzed as well. Although they showed a reduction in PIP1 antigens, PIP2 protein expression was not altered (Fig. 41). Thus, PIP1 levels are dependent on PIP2;1 or PIP2;2 proteins, whereas the reverse seems not to be the case. However, since antisera were not specific to one PIP2 isoform, it cannot be excluded that the expression of some PIP2 members is reduced, while the expression of another is increased at the same time.

**Figure 41. PIP protein expression level in *pip2* knockout mutants in roots.**

(a) Microsomal fractions were extracted from roots. The fractions were separated on a 12% SDS-PAGE and blotted onto PVDF membrane. Membranes were probed with rabbit anti-PIP2;2 or anti-PIP1;1 antisera and visualized using secondary Cy5-linked anti-rabbit antibodies and fluorescence scanning (Method 2.2.6.9). (b) Signal intensity was quantified using imageJ software. Values for each sample are expressed as a percentage of the wild-type value. Means  $\pm$  SD are shown for two independent biological experiments that were separated, blotted and analyzed at least twice. For *pip2;5-1*, *pip2;6-2*, and *pip2;8-1*, data represent two independent blots of the same protein preparation. Asterisks above bars indicate statistically significant differences based on two-sided Student's T-test assuming unequal variance (\* for  $p < 0.025$ ).

Preliminary, similar results have been observed in leaves for *pip2;1* mutants which also showed a significant reduction of PIP1 protein (Fig. 42). Several double mutants obtained by crossing *pip2;1* single mutants with other *pip2* single mutants also showed a reduction, which, at least for *pip2;2-3/pip2;1-2*, was even stronger than the single mutants alone (Fig. 42).

**Figure 42. PIP protein expression level in *pip2* knockout mutants in leaves.**

Microsomal fractions were isolated from *Arabidopsis* leaves, separated on a 12% SDS-PAGE and blotted onto PVDF membrane. Membrane were probed with rabbit anti-PIP2;2 or anti-PIP1;1 antisera and visualized using secondary Cy5-linked anti-rabbit antibodies and fluorescence scanning (Method 2.2.6.9). Signals intensity was quantified using ImageJ software. Values for each sample are expressed as a ratio *pip2* mutant/wild-type. Single mutants as well as three double mutants are shown. It should be noted that these results are based on a single experiment.

In conclusion, PIP2 protein expression, in particular PIP2;1 levels, have an effect on PIP1 protein amounts, whereas no changes were observed at the transcription level for the same knockout mutants. Hence, the down-regulation of PIP had occurred at the post-transcriptional level and lack of PIP2 could negatively influence PIP1 protein amounts.

## 4 DISCUSSION

Despite the rapidly expanding literature on the isolation and regulation of aquaporins in various plant species, reports demonstrating the functions of individual *PIP* isoform in higher plants are limited to a mutation of a single PIP1 homolog in Brassica (Ikeda et al., 1997) and a single *pip2;2* knock-out line in *Arabidopsis* (Javot et al., 2003; see Introduction). Furthermore, the high isoform multiplicity may suggest that PIP2 aquaporins display functional redundancy. In the present study, several lines of evidence were elaborated arguing in favor of differential functions for the single *Arabidopsis PIP2* genes based on various expression analyses and *pip2* knockout mutants (Table 13): (1) *PIP2* genes exhibit differential expression pattern; based on these *in situ* expression analyses the integration of PIP2 members in plant water relations was tackled. In addition, the impact of two individual PIP2 proteins on plant water transport was demonstrated via translocation of D<sub>2</sub>O through the roots into the leaves of *pip2* knockout mutant plants. (2) *PIP2* genes and *pip2* knockout mutants show differential stress-responsiveness, (3) *PIP2* genes and *pip2* knockout mutants display distinct co-expression and transcriptional profiles, respectively, and (4) *PIP2* genes are distinctly co-regulated with other *MIP* genes. Surprisingly, specific PIP2 proteins differentially influenced PIP1 expression at the protein level.

### 4.1 Distinct *PIP2* localizations allow for differential roles in water relation

The detailed promoter-reporter analysis presented here indicated a differential expression profile of *Arabidopsis PIP2* genes, which was in accordance with data based on array hybridization or RT-PCR at whole organ levels and in fluorescence-sorted root cells (Affenzeller, 2003; Alexandersson *et al.*, 2005; Birnbaum *et al.*, 2003; Boursiac *et al.*, 2005; Jang *et al.*, 2004; Schmid *et al.* 2005). Most *PIP2* genes exhibit a wide-spread organ expression pattern, but several members show predominant expression in roots (*PIP2;4*), young (*PIP2;6*) or emerging (*PIP2;8*) leaves. However, the cellular expression profile of individual *PIP2* aquaporins revealed significant additional differences.

Several transgenic lines constitutively altering PIP expression had supported their importance for plant water relations, yet did not allow to pinpoint roles of individual PIP members (see Introduction). Thus, provided that PIP2 indeed function as water channels (see below), their individual expression patterns would also suggest or preclude roles in water permeation like cellular osmoregulation, transcellular water transport, or cell growth.

All *PIP2* genes were expressed in the root hair zone and – except *PIP2;5* and *PIP2;6* – in root hairs themselves. This observation would comply with a function in absorption and/or conduction within this area most actively involved in nutrient and water uptake. Despite their biochemical function as water channels it has been questioned whether the sole function of PIP and aquaporins in general would be the enhancement of water permeation across membranes, since in several instances the reason for such a higher water conductance is obscure (Schäffner, 1998; Tyerman et al., 2002; Hill et al., 2004). Hill et al. (2004) proposed an alternative function for aquaporins as osmotic sensors. Although there is no supporting experimental evidence to date, the localization of the *PIP2* transcripts could allow such a role in the root hair cells exposed to the surrounding soil. In addition to root hair cells *PIP2;4* is the only *PIP2* that was specifically expressed in the roots including its outer cell layers, which would allow a role as an osmosensor as well as a specific function in transcellular water transport across the outer root cell layers. Interestingly, genes assigned to stress category were significantly co-expressed with *PIP2;4* (Tables 10, 13; Supplementary Table 6).

Abundant expression of *PIP2;1*, *PIP2;2* and *PIP2;7* and at a lower level *PIP2;3*, *PIP2;5*, and *PIP2;6* in vascular tissue in roots as well as in leaves could indicate that these genes exert functions in water loading into and disposal from vascular tissue in the whole plant, which is coupled to osmotic differences generated by active transport of ions or photosynthates (Fig. 8; Table 13). In the root, *PIP2;1*, *PIP2;2*, *PIP2;4*, *PIP2;5*, and *PIP2;7* could be involved in the water passage across endodermal cells with *PIP2;2* and *PIP2;4* being localized to the cortex layer as well. *PIP2;2* had been previously related to root water uptake, since *pip2;2* knock-outs had shown reduced root exudation (Javot and Maurel, 2002).

Several aquaporin genes, e.g. *PIP2;5* and *PIP2;6*, have been shown to be deregulated in roots upon nematode infestation (Puthoff et al., 2003; Hammes et al., 2005; Jammes et al., 2005). *PIP2;6* was significantly induced throughout infested root while *PIP2;5* was preferentially induced in galls, including in giant cells (Hammes et al., 2005; Jammes et al., 2005). It is well known that giant cells are metabolically very active and, hence, that large amounts of water and solutes transport are required for gall development. Thus, the induction of aquaporin genes, in particular *PIP2;5*, under these conditions may suggest functions for these proteins in growth control and/ or cell osmoregulation via regulation of plasma membrane water permeability.

In particular in younger leaves the expression of *PIP2;1*, *PIP2;2*, *PIP2;6* and *PIP2;7* extended into the mesophyll, which would allow a main function in leaf water relations. In young seedlings *PIP2;6* was the only *PIP2* gene predominantly expressed in leaves.

Interestingly, genes related to photosynthesis were significantly enriched among genes co-expressed with *PIP2;6* and to a lesser extent with *PIP2;1* and *PIP2;7/2;8*. In addition, a significant link to genes involved in primary cell-wall biosynthesis could be deduced for *PIP2;6* from AtGenExpress biotic stress datasets. Thus, a role of *PIP2;6* in growth and osmoregulation as well as in transpiration could be postulated among water related processes. *PIP2;5*'s expression in leaves would allow a similar function, although it showed a clearly distinct regulation and correlation of its expression.

In addition to its weak expression in the stele of roots similar to *PIP2;3*, *PIP2;8* could be involved in cellular osmoregulation and leaf growth at early stages (Fig. 8; Table 13). *PIP2;8* as well as *PIP2;1*, *PIP1;1*, *PIP1;2*, *PIP1;3*, and three *TIP* genes had been previously associated with growth, because reduced transcript levels were found in *cbb* mutants impaired in brassinosteroid-dependent cell elongation (Lisso et al., 2005). Interestingly, co-expression analyses also revealed a correlation of *PIP2;7/2;8* with brassinosteroid-associated and cell wall-related genes and, importantly with *PIP2;1*, *PIP1;2*, *PIP1;3*, and two of the *TIP* genes (Tables 10 and 13; Supplementary Table 3). Notably, abundant expression of several of these genes, *TIP1;1*, *TIP2;1* and *PIP1;2*, in growing/developing tissues, i.e. undergoing rapid growth have been demonstrated previously (Ludevid et al., 1992; Kaldenhoff et al., 1995; Daniels et al., 1996).

Eventually, *PIP2* genes showed a complex and differential expression in different parts of flowers, where water channels could be involved in pollen hydration and growth or in osmoregulation during deposition of nutrients. An implication for PIP aquaporins in such processes has been suggested in tobacco and tulip (Azad et al., 2004; Bots et al., 2005a; Bots et al., 2005b).

#### **4.2 Establishment of a method for assessing in vivo plant water transport**

So far, several methods have been used to assess aquaporin water permeability and function in plant water relation. At the cellular level, expression in heterologous system such as *Xenopus* oocytes (Maurel et al., 1993; Fetter et al., 2004; Temmei et al., 2005) or yeast (Loque et al., 2005; Bienert et al., 2006; Daniels et al., 2006) is widely used to functionally characterized aquaporin. Although helpful to determine the specificity of aquaporins, these systems are far from natural systems. The use of plant protoplast for single cell assay offers similar characteristic with the advantage of being in a plant cell environment (Kaldenhoff et al., 1998; Verkman, 2000). The involvement of aquaporins in plant water transport has also been investigated by measurement of hydraulic conductivity of plant organs and single cells.

For instance, pressure probes offer the advantage to continuously measure and manipulate the hydrostatic pressure of a single plant cell *in situ* but also of a whole tissue (Javot et al., 2003). At the organ level, root sap exudation measurement has proven useful to determine the contribution of PIP2;2 in water conductivity of whole *Arabidopsis* root water transport (Javot et al., 2003). A major disadvantage of these techniques is that plants are manipulated during the experiment or even destructed by decapitation, e.g. roots are separated from the leaves, for which water transport cannot be evaluated. Studies using the whole plant are a pre-requisite for an integrated knowledge of plant water relations. The use of stable isotopes as tracers is valuable since it allows dynamic investigations at the plant scale, which are non-destructive during the course of observation. The enrichment of naturally occurring stable isotopes of oxygen ( $^{16}\text{O}$ ,  $^{18}\text{O}$ ) and hydrogen (H, D) have been largely used in plant physiology and ecology, mainly to study transpiration and/or photosynthesis and several models based on the Craig & Gordon model of the evaporation of water from the surface of an ocean have been developed (Craig and Gordon, 1965; Farquhar et al., 1989; Flanagan et al., 1991; Roden and Ehleringer, 1999a; Cuntz et al., 2007; Farquhar et al., 2007; Santrucek et al., 2007). These models have been applied to several plant and tree species such as *Phaseolus vulgaris*, *cornus stolonifera*, water birch, cottonwood, maize or snowgum (White, 1988; Flanagan et al., 1991; Flanagan and Ehleringer, 1991; Roden and Ehleringer, 1999a; Gan et al., 2003; Santrucek et al., 2007).

Artificially enhancing the D content of the source water like in hydroponic cultures should allow studying the kinetics of establishment of a new equilibrium and thus the contribution of individual gene products to water translocation if knockout mutants were analyzed. Similar additions of  $\text{D}_2\text{O}$  to source water have been already used to study its influence on the isotopic composition of leaf water and the accuracy of the Craig and Gordon model for predicting leaf water isotopic content in a wide range of environmental conditions (Roden and Ehleringer, 1999a; Roden and Ehleringer, 1999b). The authors demonstrated that Craig and Gordon model generated good predictions of leaf water isotopic content under a wide range of environmental conditions and in various tree species (alder, water birch and cottonwood).

Here, the current models had to be adapted to this experimental set-up and to *Arabidopsis*. Importantly, a new term to account for the fraction of phloem water recirculating back to the source was incorporated in the model. This modification essentially had an influence in steady-state situations. In particular, it considerably improved the Craig and Gordon model predictions at conditions of high humidity, i.e. when transpiration is low and consequently phloem shoot-to-root flow more dominant. In case of low humidity, fraction of phloem water

is minor compared to water loss through evapotranspiration and therefore almost negligible. Since phloem back flow could not be experimentally assessed it was calculated to give a best fit to the measured values. Thus, it is important that this “phloem fraction” encompasses any other loss of leaf water in addition to phloem transport and the separately treated transpiration.

Previous studies have often shown that Craig and Gordon models poorly predict the isotopic composition of leaf water in particular when transpiration is low (Allison et al., 1985; Flanagan et al., 1991; Wang and Yakir, 1995; Wang et al., 1998; Helliker and Ehleringer, 2000). These discrepancies are usually explained by isotopic heterogeneity of leaf water (e.g. compartmentation). Our fractionation factor may also account and correct the model for such effects.

Subsequently, several plant-intrinsic parameters such as root and leaf mass were analyzed. Importantly, leaf water volume did not alter the deuterium enrichment of leaf water. Recently, sensitivity analyses of leaf water enrichment models to varying mesophyll water volume have been made in other plant species (Cuntz et al., 2007). The authors demonstrated that mesophyll water volume was not critical for the model predictions and that a mean leaf water volume is sufficient to obtain a good prediction of the isotopic water enrichment although it seemed to have some influence during night time. In our experiment rosette leaves were used and treated as an ideally mixed compartment of constant volume. Although rather an approximation of reality, this situation was fairly well suited for our data sets.

Using hydroponic *Arabidopsis* cultures water translocation was not dependent on root mass. In fact, since plants were grown hydroponically, root water availability was not limiting in our system. These results indicated that the dynamic D enrichment was dominated by properties of the leaves under these conditions.

#### **4.3 Non-invasive analyses of the impact of PIP2 on plant water translocation using *pip2* knockout mutants**

These measurements demonstrated the applicability of the method and wild-type and mutant plants were then compared. Among the three single mutants tested, *pip2;1* and *pip2;2* showed a reduction of about 20% of the leaf water isotopic enrichment indicating that water relations were altered in these *pip2* knockouts. Importantly, no phenotypical or morphological changes were observed between *pip2* mutant and wild-type plants. According to Figure 2 depicting water transport and exchange in plants, a retarded D enrichment could be explained (1) by a

drop in water supply from roots, (2) by decreasing evapotranspiration, and/or (3) by a reduction of hydraulic exchange between leaf cells.

Detached leaf assay as well as transpiration measurements indicated that water loss and transpiration rate were similar in *pip2* mutants and in wild-type plants; thus evapotranspiration should play a minor role. Likewise, the phloem fraction should be negligible since it influences steady-state rather than the D enrichment time course.

In a previous study, root sap exudation measurements indicated a decline in osmotic hydraulic conductivity of *pip2;2* mutant roots (Javot et al., 2003). This would lead to a slower deuterium enrichment of leaf water assuming that the same phenomenon arose in the analyzed mutants and conditions here. However, for this hypothesis, the relative independence of the method from root mass still remains elusive. It is so far impossible with our data to determine how important the contribution of the root to the method is.

Alternatively, the reduction could be explained by a slower water exchange between leaves cells. Indeed, *pip2* knockout may alter leaf symplastic water flow. Thus, mixing of water is slower and evapotranspiring water via apoplastic path is then enriched in deuterium (see Introduction; Fig. 2). Consequently, leaf water will reach its isotopic steady-state more slowly. Recently, an influence of PIP2 aquaporin in leaf hydraulic conductance has been demonstrated (Cochard et al., 2007). The authors correlated downregulation or upregulation of *JrPIP2;1* and *JrPIP2;2* in walnut tree leaves in response to light with a low or high leaf hydraulic conductance, respectively. Their observation could be in agreement with the knockout results of this study.

These results demonstrated the involvement of PIP2;1 and PIP2;2 in plant water relation. Yet, so far, the data are not sufficient to determine whether the decline in water translocation is caused by root and/or leaf hydraulic conductance.

It is important to note that a *pip2;4* mutant did not exhibit retarded leaf isotopic enrichment. Thus, *PIP2;4* loss-of-function did not alter water translocation. The explanation may reside in its particular expression pattern; *PIP2;4* is not expressed in leaves and is predominant in outer root cell layers, yet expression in roots is much lower compared to *PIP2;1* and *PIP2;2*.

Surprisingly, the double mutant *pip2;2-3/pip2;1-2* did not exhibit any decrease in its isotopic enrichment. While the decline observed in the single mutants indicated a disturbance in the plant water status, a phenotypical recovery was observed for the double mutant. Double mutant plants might be more severely affected than single mutant and, hence, have to develop a strategy to sustain stress and maintain a suitable water status. Consequently, the water translocation from root to shoot is unchanged and the plants would not be phenotypically

altered. To date, the explanation for such compensation is still obscure. However, such a phenomenon has already been observed using PIP antisense mutant plants (Kaldenhoff et al., 1998; Martre et al., 2002). A reduced osmotic hydraulic conductivity of root and leaf protoplasts from antisense plants with reduced amount of PIP1 and/ or PIP2 proteins was observed, while the hydraulic conductance of the whole plant was not affected (Martre et al., 2002). In fact, the authors did not observe alteration of the leaf hydraulic conductance while the root hydraulic conductivity was lower on a root dry mass basis but compensated by an increase in the root/leaf dry mass ratio.

Martre et al. (2002) used antisense constructs (*PIP1;2* and/ or *PIP2;3* cDNA) to reduce PIP protein expression. These antisense plants were characterized by reduction of several isoforms and therefore our *pip2;2-3/ pip2;1-2* double mutant may represent a slightly comparable situation. Nevertheless, our mutant is likely not as strongly disturbed as Martre et al. (2002) mutants since they observed a greater root dry mass to compensate for the lower root hydraulic conductance. Indeed, the increase or decrease of aquaporins in transgenic plants is hypothesized to increase or decrease root water permeability resulting in a smaller or larger root area to maintain a constant water uptake by roots, respectively (reviewed by Hachez et al., 2006a). However, no differences in root and shoot mass were observed in *pip2;2-3/ pip2;1-2* mutant. Possibly, in this mutant, a smaller root area was sufficient to supply enough water into the aerial parts. It may well be that in our hydroponic culture, double mutants do not need to adjust its root area to compensate for any reduction in root conductance but rather could optimize the uptake since water was not limiting under these conditions.

#### 4.4 *PIP2s* differentially respond to stress

Several reports have shown the differential responsiveness of *PIP* genes to water stresses as well as to biotic cues or plant hormones (Kreps et al., 2002; Seki et al., 2002a; Seki et al., 2002b; Affenzeller, 2003; Maathuis et al., 2003; Jang et al., 2004; Kawaguchi et al., 2004; Alexandersson et al., 2005; Boursiac et al., 2005). However, in some instances, there is no agreement concerning the *PIP* members which are altered. For instance, Alexandersson et al. (2005) observed a strong down-regulation of *PIP2;2* upon drought stress while it was upregulated in another study (Kreps et al., 2002). Likewise, *PIP2;3* and *PIP2;6* were either upregulated (Seki et al., 2002a), downregulated (Jang et al., 2004) or not markedly altered (Alexandersson et al., 2005) upon drought stress. In contrast, Alexandersson et al. (2005) pointed out that *PIP1;4* and *PIP2;5* were consistently upregulated upon drought in these studies. These divergent results were mostly explained by experimental differences (e.g.

growth conditions, severity and duration of the stress). In this respect, the AtGenExpress consortium provided important information on plant stress responses under various treatments using Affymetrix microarray expression profiling (Kilian et al., 2007), which also supported the specific transcriptional deregulations of *PIP2* genes. Interestingly, *PIP2;2/2;3*, *PIP2;4* and *PIP2;5* were more frequently deregulated than other *PIP2* members, yet showed mostly responses to different cues (Supplementary Table 9). As a consequence, PCA based on these data demonstrated distinct stress-responsiveness. *PIP2* genes showed mostly opposite or independent projections and only *PIP2;1* and *PIP2;7/2;8* or *PIP2;2/2;3* and *PIP2;4* in context with *PIP1* genes were grouped together (Figure 35). On the other hand, *PIP1* genes themselves were associated with distinct *PIP2* groups or partially independent from these response patterns. Thus, these results do support the independent evolvement of stress responsiveness of *PIP2* as well as *PIP1* members and, consequently, gene-specific, non-redundant functions related to distinct stresses. PCA also highlighted stresses which contributed most to the *PIP2* differentiation. For instance, upregulation of *PIP2;5* under salt, osmotic or cold stress contributed to the particular pattern of this isoform. Such upregulation has been consistently demonstrated by other groups (Jang et al., 2004; Alexandersson et al., 2005). In addition enhanced GUS activity in transgenic seedlings expressing a *PIP2;5* promoter::GUS construct after several days of growth under salt stress was found, while seedlings grown on sorbitol did not show significant increase (See Annex 2 data *PIP2;5*).

#### 4.5 *PIP2;3* specifically required for NaCl resistance

Although *PIP* transcripts responded to salt or osmotic stresses and complex alterations of *PIP* expression in transgenic (overexpression and suppression) lines changed sensitivity towards water stresses, individual *PIP* functions had not been related to sensitivity towards osmotic or ionic stresses. A wide-spread down-regulation of *MIPs* genes was usually observed upon drought and osmotic stresses (Alexandersson et al., 2005; Jang et al., 2004) and may explain why none of the *pip2* knockouts showed enhanced sensitivity to sorbitol or mannitol; yet, enhanced resistance was not observed either. Surprisingly *pip2;3* mutants were sensitive to enhanced NaCl, whereas none of the other *pip2* mutants were affected. Indeed, mostly transient up-regulation of *PIP2;3* gene expression upon salt stress had been reported in roots or leaves (Boursiac et al., 2005; Jang et al., 2004; Maathuis et al., 2003), although adult plants did not show such a response (Affenzeller, 2003).

However in these contributions, transcription was analyzed shortly after salt treatment (2 to 96 h) implying a possible influence of *PIP2;3* in short-term ionic or purely osmotic stress

response. In contrast, our loss-of-function experiments indicated that *PIP2;3* expression was important to cope with a long-term challenge by enhanced NaCl irrespective of the osmotic stress. Importantly, there was no transcriptional compensation of *pip2;3* by any other aquaporin, in particular by its closest homologue *PIP2;2* (Table 8). In a previous report, *Arabidopsis pip2;2* knockout mutants did not show growth or developmental alterations under standard as well as water stress conditions but exhibited reduced root water uptake and endogenous *PIP* transcripts including *PIP2;3* were not altered either (Javot et al., 2003). Consequently, *PIP2;2* is mainly involved in water uptake, whereas *PIP2;3* has evolved with a non-redundant function and is specifically required for salt stress resistance in *Arabidopsis*.

The high homology of *PIP2;2* and *PIP2;3*, their water channel activity in *Xenopus* oocytes as well as their overlapping expression pattern in vegetative tissues strikingly contrasts such a differential function. Furthermore *PIP2;3*'s expression level was much weaker (this work; Affenzeller, 2003; Alexandersson et al., 2005; Boursiac et al., 2005; Daniels et al., 1994; Jang et al., 2004; Kammerloher et al., 1994). Thus it seems to be unlikely that sole water transport function is the major role of *PIP2;3* in salt tolerance. Interestingly, *PIP2;3* is expressed in stomata, which control transpiration. However the phenotype has been observed on plates with a high atmospheric water saturation that should diminish the influence of transpiration. Thus, a different regulation could distinguish both genes, although *PIP2;2* and *PIP2;3* share the same 3 kb upstream region in a head-to-head orientation, or a different property of *PIP2;3* protein, which might also deviate from pure water channel activity (which would be *PIP2;2*'s part) either by allowing other molecules to permeate or through a regulatory role in salt tolerance. In fact, at least different putative transcription factor binding site could be found in the non-overlapping -1 kb upstream region of each gene (Supplementary Figure 2 and Supplementary Table 10). Only nine among 285 amino acids are altered in both proteins, yet modeling their position within the PIP structure (Törnroth-Horsefield et al., 2006) revealed that five are clustered within or in the vicinity of the extracellular loop C, where either the permeation or the interaction with extracellular partners could be influenced (Fig. 43). Two other changes are within helices 1 and 6 and might be of minor importance, although the T258 in *PIP2;3* exposes a functional group in contrast to *PIP2;2*'s A258 that could be accessed within the membrane (Fig. 43). Interestingly, contrasting mercury sensitivities had been already reported for *PIP2;2* and *PIP2;3* despite their high homology and the absolute conservation of four cysteine residues (Daniels et al., 1994; Kammerloher et al., 1994), which also hints towards a structural difference.

**Figure 43. Structural models of PIP2;2 and PIP2;3 showing their different amino acids.**

The three-dimensional structures of (a) PIP2;2 and (b) PIP2;3 were generated using SWISS-MODEL (Kopp and Schwede, 2004; Arnold et al., 2006) with the crystal structure of *SoPIP2;1* as template (PDB code: 1z98A). E9 in PIP2;2 which is replaced by D9 in PIP2;3 is not shown in the model. All other amino acids which diverge between PIP2;2 and PIP2;3 are shown and most are located within loop C or positioned nearby. Red spheres design oxygens, blue ones nitrogen, and grey ones carbon atoms; I52 and V52 in helix 1 are not coded for elements and highlighted in olive.

#### 4.6 *PIP2* genes are embedded in different functional context

Given that aquaporins facilitate the permeation of water across biological membranes a major interest is now to integrate the contribution of aquaporin-water facilitation to physiological processes. Previous reports suggested a relation between aquaporin and various biological functions of plants including transport processes, nutrient acquisition, carbon fixation and stress responses. For instance, a relation between PIP1 and photosynthesis has been suggested in tobacco (Siefritz et al., 2002; Uehlein et al., 2003; Flexas et al., 2006) and *Arabidopsis* (Aharon et al., 2003). Data on PIP2 have been much more limited. In tobacco, PIP2 members are required for efficient anther dehiscence. Therefore, two different approaches were performed to investigate the functional context in which particular *PIP2* gene may be embedded. One approach consisted of analyzing the transcriptome of *pip2* knockout mutants while the other approach focused toward co-expression analyses. It is important to note that co-expression analyses are based on genes showing a pattern of expression correlated to that of a particular *PIP2* gene in a wide range of conditions. In contrast, array analyses were done to study the effect of a particular *PIP2* mutation on other transcripts.

In the first approach, transcriptome analyses of *pip2* mutants using two different array technologies revealed only minor changes but, nevertheless, supported the differential function hypothesis. Our custom-array indicated that transport-related families are not altered

in *pip2* mutants. The results were corroborated by whole genome Affymetrix analyses of *pip2;1-2*, *pip2;2-3* and *pip2;4-1* mutants since no deregulation of transport processes was observed in these mutants. Whole genome Affymetrix analyses also revealed different transcriptional profile of *pip2* mutants. However, functional categorization of the deregulated genes did not give clear hint on processes that could be affected in *pip2* mutants. In fact, apart from *pip2;2-3/pip2;1-4* other single and double mutants tested did not exhibit significant alteration of a particular category. In *pip2;2-3/pip2;1-4* root and leaf transcriptome, the over-representation of cell wall-related genes and of transcripts encoding enzymes involved in oxidative stress response and secondary metabolism (i.e. miscellaneous category), respectively, suggested an enhanced cell wall loosening.

To gain further insights into the PIP2 family, co-expression analyses were performed. Typically, a very poor, if any, overlap was observed at the gene level between *PIP2* co-expressed genes. However, the significant enrichment of genes assigned to the functional category revealed by co-expression analyses demonstrated that *PIP2* transcripts are differentially associated with other genes that are related to different functional contexts (Table 13). Surprisingly, only *PIP2;1* and *PIP2;2/2;3* exhibited enrichment of transport category supporting our array data which showed no alteration of transporter-related transcripts. These results suggest that the role of most PIP2 may not primarily be embedded in the functional context of transport. Interestingly, several members were linked to photosynthesis and/or cell wall-related processes, possibly indicating function in growth; other members were also correlated to hormone metabolism (e.g. *PIP2;7/2;8*; Table 13) or showed a higher enrichment of stress-related genes (e.g. *PIP2;2/2;3* and *PIP2;4*) (Tables 10 and 13). These observations provide a basis for further analysis on the integrated role of single PIP2 aquaporins.

#### 4.7 Differential PIP2-MIP interactions

Relationships between PIP2 and PIP1 at both transcript and protein level were detected.

Co-expression analyses indicated differential and strong correlation of specific *PIP2* transcripts with other *PIP* and *TIP* genes in a wide range of conditions. Stress-based PCA also indicated a differential association of *PIP2* and *PIP1* genes. In fact, *PIP2* genes showed a much better correlations with *PIP1* genes than with other *PIP2* members indicated by considerably high *PIP2-PIP1* correlation coefficients for the couples *PIP2;1* vs. *PIP1;2*, *PIP2;2/2;3* vs. *PIP1;1*, or *PIP2;7/2;8* vs. *PIP1;3* ( $\tau > 0.82$ ; Tables 12 and 13). *PIP2;1*, *PIP2;2/2;3*, *PIP2;4* and *PIP2;7/2;8* also exhibited a strong correlation with several but

different *TIP* genes (Tables 12 and 13). These observations may provide an independent hint towards a partnership or functional cooperation of PIP2 isoforms with several PIP1s and TIPs members in order to maintain water status at the cellular and/ or tissue level. In fact, as a result of their subcellular localization, PIPs and TIPs are expected to function in concert in water relations. In contrast, *PIP2;5* and *PIP2;6* clearly did not show any correlations, indicating a specific role among *PIP* members (Tables 12 and 13).

Surprisingly, a direct influence of PIP2 on PIP1 protein levels was demonstrated by the specific reduction of PIP1 amounts in *pip2;1* and *pip2;2* knockout mutants. It is important to note that *pip2* mutants did not reveal significant alteration of any other *MIP* gene (this work; Javot et al., 2003). Importantly, these results pointed out the utility of knockout mutant to investigate a particular isoform contrasting to overexpression strategy (Jang et al., 2007a, b).

Recent reports demonstrated the importance of PIP2 and PIP1 protein interaction to regulate PIP1 targeting to the plasma membrane and consequently their activity (Fetter et al., 2004; Temmei et al., 2005; Zelazny et al., 2007). When expressed alone in maize protoplasts, PIP1 were not targeted to the plasma membrane, but retained in the endoplasmic reticulum. The authors speculated that PIP1 and PIP2 interaction is required for PIP1 trafficking to the plasma membrane to modulate plasma membrane permeability (Zelazny et al., 2007). In our work, the reduction of PIP1 protein level in *pip2* knockout mutants demonstrated the influence of PIP2 on PIP1 protein level. Interestingly, reduction of PIP2 protein level was not observed in two *pip1* knockout mutants suggesting that only PIP1 is regulated by PIP2;1 and PIP2;2, but the reverse may not be true. Thus, the expression level and/or stability of PIP1 protein may be closely linked to that of PIP2 proteins. Thus, a new type of interaction or a new type of regulation of expression at the protein level was identified. The dependence of PIP1 protein expression on PIP2;1 and PIP2;2 may be also related to the direct protein-protein interaction shown previously (Fetter et al., 2004; Temmei et al., 2005; Zelazny et al., 2007). PIP2-PIP1 interaction/heteromerization enhances PIP1 targeting to the plasma membrane and/or its stability and such heteromerization may lead to structural changes implicated in regulation of PIP activity (Chaumont et al., 2005; Zelazny et al., 2007). The present study suggests that PIP1 stability is altered; PIP1 is rather degraded than simply mistargeted to other membranes, because microsomal fractions were analyzed.

An important issue to address is whether this regulation process affects all or only particular PIP1 isoforms. Co-expression of both *AtPIP1;3* and *ZmPIP1;2* in *Xenopus* oocytes resulted in an increase in water permeability (Fetter et al., 2004) and sequence comparison of PIPs indicates that all *Arabidopsis* isoforms harbor the critical amino acid residues which could be

responsible for the interaction as proposed by Fetter et al. (2004). *In planta*, such interactions/regulations would require a similar spatial expression of the genes in order to have a potential functional relevance. Interestingly, *PIP1;1*, *PIP1;2* and *PIP1;3* showed an extremely similar expression pattern and high correlation with *PIP2;1*, *PIP2;2/2;3* and *PIP2;7/2;8* suggesting that isoforms such as these PIP1 isoforms could potentially be involved. The presence of *PIP2;1*, *PIP2;6*, *PIP2;7* and *PIP2;8* as well as *PIP1;1*, *PIP1;2*, *PIP1;3* and *PIP1;5* has been demonstrated in detergent resistant membranes (i.e. lipid rafts) (Mongrand et al., 2004; Shahollari et al., 2004; Bhat and Panstruga, 2005).

#### 4.8 Conclusion

This work demonstrated that the closely related PIP2 members exhibit differential functions. In addition, the functional context of single PIP2 members has been exposed and *PIP2;3* has even been associated to salt stress. Such classification could definitely help identifying the physiological involvement of aquaporin in different key processes, e.g. elongation (*PIP2;8*) or photosynthesis (e.g. *PIP2;6*) and, consequently, provides a framework for future prospects. Complete characterizations whether any *PIP2* promoter are activated or repressed by stress or other treatments are still required for a clear distinction regarding different PIP2 isoforms. Importantly, this study pointed out the utility of knockout mutant for the functional analysis of single PIP2 aquaporins demonstrating that even highly homologous isoforms (e.g. *PIP2;2* and *PIP2;3*) exhibit non-redundant functions.

Aquaporins have been suggested to act as multifunctional channels but the lack of characterization of transport selectivity renders a complete comprehensive analysis difficult. In fact, aquaporins are often characterized exclusively in terms of their water transport ability; although a water channel activity has not been experimentally proven for most of them. The number of PIP2 isoforms in plants raises the question whether water is the only molecule capable of transiting through aquaporins, e.g. for *PIP2;3*, and what would be the physiological relevance of such permeation should be of major interest in future prospects?

A transcriptional interrelation of *PIPs* and even *TIPs* as well as a PIP protein relationship has been brought to light suggesting complex regulatory mechanisms. Several *MIPs* isoforms may work in combination for the maintenance of plant water status. Analysis of single and multiple knockout mutants (both *PIPs* and *TIPs*) and the effect of a particular *MIP* member on others may help integrate and interpret the function of plant aquaporins.

Eventually, the method using deuterated water as a tracer adapted in this study has proven useful and demonstrated that single aquaporin, i.e. *PIP2;1* or *PIP2;2* are involved in plant

---

water relations. Experiments isolating roots or leaves from each other could help to elucidate whether and to what extent PIP2 aquaporins contribute to root water uptake and/ or leaves hydraulic exchange.

**Table 13. *Arabidopsis* PIP2 isoform classification.**

<sup>1</sup>Using array hybridization Leonhardt et al. (2004) found weak evidence for *PIP2;1* transcripts in a guard cell fraction and for *PIP2;1*, *PIP2;2*, *PIP2;6*, and *PIP2;7* transcripts in mesophyll cells. <sup>2</sup>Abbreviations: D drought, H heat, C cold, O Osmotic, S Salt, *B.c.* *Botrytis cinerea*, *P.i.* *Phytophthora infestans*, *P.s.* *Pseudomonas syringae*, A Auxin, AT Auxin transport, ATI Auxin transport inhibitor, ET Ethylene inhibitor, CW Cell wall, HM Hormone metabolism, MC miscellaneous, PS Photosynthesis, RX redox, SA salicylic acid, ST stress, TP, transport. Arrows indicate up- or downregulation of transcripts.

## 6 SUPPLEMENTARY MATERIAL AND ANNEXES

**Supplementary Figure 1.** Histochemical localization of PIP2::GUS activity in siliques. Expression in siliques of 5- to 6-week-old plants grown in soil expressing *PIP2* promoter::GUS constructs: (a) *PIP2;1*, (b) *PIP2;2*, (c) *PIP2;3* (d) *PIP2;4*, (e) *PIP2;5*, (f) *PIP2;6*, (g) *PIP2;7*, and (h) *PIP2;8* promoter::GUS.

**Supplementary Figure 2.** Differential representation of promoter elements in *PIP2;3 (RD28)* vs. *PIP2;2 (PIP2B)*. **(a)** The regions -1000 until +100 with respect to the translation start site were examined for differential representation of all 68 families of plant transcription factor binding sites at MatInspector at [www.genomatix.de](http://www.genomatix.de). Differentially represented or arranged binding sites according to Supplementary Table 10 are depicted. **(b)** In addition to these differences, several framework motifs (i.e. combinations of binding sites with similar relative order and spacing) are found with FrameWorker at [www.genomatix.de](http://www.genomatix.de). **(c)** Shows an example of a randomly selected framework (1 out of 11 frameworks with up to 7 binding sites) consisting of seven binding sites. Interestingly, the included CCAF motif was also identified as a part of a differential representation and clustering of motifs (Supplementary Table 10).

**Supplementary Table 1.** Membrane transport-related gene expression in roots of *pip2* insertional mutants. Wild-type and *pip2* mutants were grown hydroponically for 3 weeks and root expression of about 500 transport-related genes were analyzed using a custom cDNA array harboring gene-specific 3'-UTR probes compiled within the DFG Priority program SPP1108 (Van der Graf, E., Kunze, R., Flügge, U., Neuschaefer-Rube, O. and Schäffner, A.R., unpublished; Glombitza et al., 2004; probe sequences are available upon request to schaeffner@helmholtz-muenchen.de). Two biologically independent replicates of twelve mutants and Columbia wild-type were analyzed. Signal intensity of each gene in the mutant plants was compared with the signal intensity of the same gene in the wild-type plants to calculate an expression ratio (mutant *versus* wild-type). Fold-changes (FC) were calculated by averaging expression ratios of the two biologically independent replica of two independent mutants each with the exception of *pip2;4* and *pip2;8*, for which only one mutant was available. Consequently, only genes consistently deregulated in both mutants were to be considered as significant changes.

SD: standard deviation. n.d.: not detected

(A) *MIP* gene expression. Probes corresponding to 3'-UTR regions detected *PIP2* transcripts of several knocked out genes similar to the wild-type. However, the loss of complete transcripts of the respective *PIP2* genes had been clearly demonstrated by RT-PCR with primers flanking the insertion site.

(B) Expression ratios for additional genes analyzed.

**Supplementary Table 2.** Top hundred deregulated genes in various *pip2* knockout mutants. Mutants transcriptional profile were analyzed using Affymetrix ATH1 GeneChip. After statistical analyses, differentially expressed genes were extracted and the top hundred were submitted to functional classification according to MapMan. Expression ratios are expressed as log2 values.

mutant	ROOTS										LEAVES										Functional categories	description	
	pip 2:1	wt	ratio 2:1/wt	p- value	pip 2:2	wt	ratio pip2:2/ wt	p- value	pip 2:4	wt	ratio pip2:4/ wt	p- value	pip 2:1- 2:4	wt	ratio 2:1- 2:4/wt	p- value	pip 2:2- 2:1	wt	ratio 2:2- 2:1/wt	p- value

**Supplementary Table 3.** Functional categories according to MapMan classification (Thimm et al., 2004) of genes co-regulated with *PIP2* genes retrieved from ACT. Italic labeling indicates probesets that recognize several genes. Genes co-expressed with several *PIP2* genes are compiled separately as well.

**PIP2;1 (251962\_at/ At3g534207)**

**Supplementary Table 4 to 8. *PIP2* correlated genes classified into functional categories based on MapMan (Thimm et al., 2004).** Correlated genes were retrieved at BAR using distinct AtGenExpress array datasets. All datasets showing *PIP2* correlated genes with a Pearson correlation coefficient above 0.6 (or below 0.6 for negative correlation) were analyzed. For each category, percentage relative to all genes in the column, the number of assigned genes (in brackets) is indicated. Significance of over-representation for each functional category was determined using a Fisher's exact test (two-sided). The asterisks denote different levels of significance based on p-values (two-sided Fisher's Exact test; Methods 2.2.10): \*\*\* <  $10^{-10}$ , \*\* <  $10^{-5}$ , and \* < 0.002. +/- correspond to positively or negatively correlated gene lists, respectively.

Supplementary Table 4. Functional categories assignment of *PIP2;1* correlated genes.

Category	Expected Frequency	Observed Frequency						
		Whole genome (MapMan)	Abiotic root + (out of 39)	Abiotic shoot + (out of 198)	Hormone + (out of 116)	Biotic + (out of 404)	Biotic – (out of 162)	Abiotic shoot – (out of 171)

**Supplementary Table 10.** Promoter elements in *PIP2;2* and *PIP2;3*. (a) A summary of the families related to transcription factor binding sites that were found in both promoters with -1000 and +100 bp sequences with respect to the translation start site. Families labelled in bold were selected and depicted in Supplementary Figure 2. (b) All individual sites for both promoters are listed with their exact position, sequence and similarities to both the consensus matrix and the four-nucleotide core sequence. In a few cases (e.g. CCAF) the same number of sites were found, yet with a different distribution.

[MatInspectorprofessional 7.6.2, November 2007; Search Jan 17, 2008 at [www.genomatix.de](http://www.genomatix.de)].

### Annex 2. Data *PIP2;5*

Interestingly, the *pip2;5-1* mutant showed a drastic salt sensitivity. This mutant did not show any phenotype under normal growth as well as under purely osmotic stress (see Results 3.3). However, this mutant exhibited additional T-DNA insertions as shown by Southern blotting (see Results 3.2) and the phenotype was not confirmed by a second independent T-DNA insertional mutant (Results 3.3). Hence, a involvement of *PIP2;5* in salt resistance seemed to be less likely; yet the interesting phenotype possibly due to another mutation was examined in more detail.

First, the salt sensitivity had been observed with NaCl. Thus, to check whether this sensitivity was specific to NaCl or could be extended to other salts, growth of *pip2;5-1* mutant under potassium chloride stress (KCl) was assessed. Interestingly, the reduced growth observed under NaCl stress was also observed under KCl stress arguing against a sole  $\text{Na}^+$  toxicity (Fig. 1).

**Figure 1. Root elongation of wild-type and *pip2;5-1* mutant under salt stress.**

Four-day-old seedlings germinated in standard medium were transferred to vertically orientated plates containing various salt: (a) 50 mM NaCl; (b) 100 mM NaCl; (c) 50 mM KCl and (d) 100 mM KCl. Seedlings were grown for 7 additional days and root elongation was recorded daily. Symbols are means  $\pm$  SDs of 6 to 7 plants.

Both salts provoked reduced growth to a similar extent with a slight reduction under 50 mM salt (Fig. 1a and c) and an often lethal phenotype under 100 mM salt (Fig. 1b and d). It is noteworthy that the phenotype observed for *pip2;5-1* seems to be the consequence of the duration of the stress since normal growth was observed during the first days of stress. The first symptoms of death appeared only after 2 to 3 days of growth under salt stress (Fig. 1).

In addition, *pip2;5-1* mutant was grown on enhanced, isoosmotic 200 mM mannitol to check sensitivity under purely osmotic stress. The use of mannitol, similar to sorbitol, did not lead to the strong phenotype observed with salt indicating that *pip2;5-1* was exclusively salt sensitive (Fig. 2).

**Figure 2. Root elongation of wild-type and *pip2;5-1* mutant under Mannitol.**

Four-day-old seedlings germinated in standard medium were transferred to vertically orientated plates containing 200 mM Mannitol. Seedlings were grown for 7 additional days; root elongation was recorded daily (left panel) and plants were photographed (right panel). Symbols are means  $\pm$  SDs of 6 to 7 plants.

Since the *pip2;5-1* mutant has additional T-DNA insertions, the line showing the phenotype has been backcrossed into wild-type in order to get rid of additional insertions. Five lines have been recovered from these backcrosses and their segregation on BASTA selection indicated a 1:5 segregation suggesting that these five backcrossed lines may contain a single T-DNA insert. All five lines showed the lethal phenotype previously observed when grown in presence of high NaCl concentration whereas a hemizygous line did not exhibit salt sensitivity (Fig. 3).

**Figure 3. Several *pip2;5-1* backcrossed mutant lines exhibit salt sensitivity.**

Six *pip2;5* backcrossed mutant lines were grown under salt stress (100 mM NaCl). Lines 4 to 36 were homozygous and exhibited salt sensitivity whereas a hemizygous line (line 43) did not exhibit any phenotype.

Furthermore, transgenic plants expressing a *PIP2;5* promoter::GUS fusion protein were used to investigate *PIP2;5* expression under salt stress. Expression of *PIP2;5* in seedlings grown on standard medium was compared with *PIP2;5* expression in seedlings grown under osmotic and salt stress conditions to check whether these conditions would alter *PIP2;5* expression in plants. The histochemical GUS assay was carried out on transgenic seedlings. An induction of GUS activity was observed in leaves when seedlings were submitted to 100 mM NaCl stress but not with 200 mM sorbitol (Fig. 4). Indeed, 4 days-old transgenic plants expressing a *PIP2;5* promoter::GUS construct were transferred to vertical plates containing 100 mM NaCl or 200 mM Sorbitol and GUS expression was tested after 1 day and after 6 days. As a control, transgenic plants were also transferred in plates containing standard medium. Interestingly, no differences were observed after 1 day. Similar GUS expression could be detected in both seedlings grown in standard medium as well as in water stress medium (data not shown). However, after 6 days, transgenic seedlings exhibited a differential response. Although GUS activity was detected in control seedlings as well as in stress conditions, GUS activity was stronger in seedlings grown under salt stress (100 mM NaCl) than in seedlings grown under standard or osmotic stress conditions (Fig. 4). These results indicate that *PIP2;5* responds to water stress provoked by salt.

**Figure 4. Histochemical GUS analysis of transgenic plants expressing a *PIP2;5* promoter::GUS fusion protein.**

GUS activity was tested in transgenic seedlings grown under normal and water stress conditions. Different lines were tested and exhibited similar results although expression level was different.

All together, these observations suggested an involvement of *PIP2;5* to withstand salt stress (in particular ionic stress). Indeed, several backcrossed lines for which segregation analyses indicated a single insertion showed a strong phenotype when grown under salt stress. GUS analyses revealed induction of *PIP2;5* after salt exposure. However, this phenotype was only observed with the particular *pip2;5-1* mutant and was not confirmed by a second independent mutant (*pip2;5-3*, see Results 3.3). Genomic analyses revealed that *pip2;5-1* mutant carried additional insertions. Therefore, complementation analyses were performed to test whether there could be any correlation of salt sensitivity and *pip2;5* knock-out. Complementation analyses constitute the ultimate proof to link the observed phenotype to *PIP2;5* loss-of-function. Hence, the *PIP2;5* genomic region was introduced into *pip2;5-1* mutant plants. Transformed plants were selected by their resistance to kanamycin and the presence and expression of the transgene in these plants were confirmed by PCR amplification of the *PIP2;5* cDNA (Fig. 5a). Transformed lines carrying the introduced *PIP2;5* genomic sequence were then tested for their salt sensitivity. The complementation did not rescue the phenotype of *pip2;5-1* plants suggesting that *PIP2;5* is probably not, at least not directly and/or not alone, responsible of the salt sensitivity observed (Fig. 5b).

**Figure 5. *PIP2;5* genomic sequence does not rescue *pip2;5-1* salt phenotype.**

**(a)** Agarose gel electrophoresis of Col-0 (1), *pip2;5-1* mutant (2) and *PIP2;5* complemented plants (C2-C3) cDNA amplification products. Total RNA was isolated from *Arabidopsis* seedlings and cDNA synthesized. Amplification products were further visualized by ethidium bromide staining. For control, cDNA fragments for Tubulin (*TUB9*, At4g20890) were amplified. Expression of the *PIP2;5* gene was not detectable in *pip2;5-1* mutant whereas it was detected in col-0 wt and complemented plants. No signals were detected in the controls (-RT; not shown).

**(b)** wt, complemented plant and *pip2;5-1* mutant seedlings grown on 100 mM NaCl. Four-day-old seedlings germinated in standard medium were transferred to vertically orientated plates containing 100 mM NaCl and further grown for 7 days.

To conclude, a salt sensitivity was observed for a particular *pip2;5-1* but could not be complemented by *PIP2;5* coding sequence. The *pip2;5-1* phenotype was still observed after backcrosses for homozygous lines, while hemizygous lines did not exhibit the phenotype. Molecular characterization of *pip2;5-1* mutant indicated additional T-DNA insertion but the integrity of the genome flanking *PIP2;5* gene was confirmed by PCR and restriction digest (see Results 3.2). Thus, all these results suggest that the *pip2;5-1* phenotype could be the result of the mutation of a single recessive gene which might be closely linked to *PIP2;5* gene. It is noteworthy that a second mutant, *pip2;5-2*, was strongly growth retarded. The salt sensitivity of this *pip2;5-2* mutant could not be tested since four-day-old seedlings did not have cotyledons, while root growth was relatively normal. Cotyledons were fully developed only after about 7 days and then this mutant could not be compared with any other genotype. Nevertheless, *pip2;5-1* and *pip2;5-2* mutants showed a T-DNA insertion in the first exon and oriented in the same direction (see Results 3.2, Fig. 17). Hence, it may well be that the T-DNA insertion in this region alters another part of the genome.

**ACKNOWLEDGEMENTS**

First and foremost, I would like to express my sincerest gratitude to my advisor, PD. Dr. Anton R. Schäffner, for sharing his insight and knowledge and for his wonderful guidance during my whole program of study. His enthusiasm and encouragement made the entire Ph.D study very much enjoyable. He offered me key ideas, inspiration and encouragement in tackling with my thesis problems, which I deeply appreciate. His critical reading and sharp comments made this dissertation more rigorous.

My thanks are extended to Prof. Karl-Peter Hopfner and to the other committee members for their careful reading and valuable comments on this dissertation.

I am very much grateful to Dr. Willibald Stichler, Institute for Ground Water Ecology (Helmholtz Zentrum München) and Dr. Wolfgang Graf, Institute for Soil Ecology - Department of Environmental Engineering (Helmholtz Zentrum München) for their help in establishing the water translocation experimental set-up, samples measurements and critical reading of the dissertation.

I am thankful to Dr. Barbro Winkler and to Dr. Andreas Albert, Institute for Soil Ecology - Department of Environmental Engineering (Helmholtz Zentrum München) for their help in transpiration measurements and sun simulator experiments.

I wish to express my gratitude to Dr. Michael T. Mader, Institute of Stem Cell Research (Helmholtz Zentrum München), Dr. Gerhard Welzl, Institute of Developmental Genetics (Helmholtz Zentrum München) for their precious help in statistical analysis of array data.

I thank Sebastian Gresset for his help in GUS histochemical and *pip2* mutants' phenotypical analyses.

I would like to express my gratitude to all individuals, too many to name who helped making this dissertation possible.

I also thank my friends, and staff at "BIOP". In particular, my special thanks go to Birgit Geist for her assistance during the whole Ph.D. program and to Andi and Cristina for their friendship and support.

I thank the Deutsche Forschungsgemeinschaft (DFG) within priority program 1108 (Scha 454/8) for financial support.

---

Finally, I thank my family and friends for their endless and unselfish support throughout. Particularly, I am grateful for the love and concerns of my parents, my sister Julie, my brother David, and my Girlfriend Mercedes. Completing the Ph.D. would have been impossible without their love and encouragement.

## CURRICULUM VITAE

### PERSONAL DETAILS

Name	DA INES Olivier
Date of birth	June 19, 1978
Place of birth	Mâcon (France)
Nationality	French
Marital status	Single

### EDUCATION

11/2003- 05/2008      Ph.D. at the Ludwig-Maximilians University, Munich, Germany.  
Title: “Functional Analysis of PIP2 Aquaporins in *Arabidopsis thaliana*”. Advisor: PD. Dr. Anton R. Schäffner. Helmholtz Zentrum München. German Research Center for Environmental Health. Neuherberg, Germany. Institute for Biochemical Plant Pathology.

2001-2003              Master of Science (Biochemistry, Cellular and Molecular Biology)  
University of Burgundy, France.

1999-2001              Bachelor of Science (Biochemistry degree)  
University of Burgundy, France.

1997-1999              Pharmaceutical School  
University of Burgundy, France.

1993-1997              Mathematics, Physics, Chemistry and Life Sciences  
Lycée Lamartine, Mâcon, France.

### PROFESSIONAL EXPERIENCE

2002-2003. **Master Thesis** on UMR INRA/CNRS Plante-Microbe-Environnement. University of Burgundy, France. Title: “Modulation of Tonoplast Aquaporins expression in *Arabidopsis thaliana* using sense and anti-sense strategies”. Advisor: Prof. Francis Marty; Supervisor: Dr. Karim Bouhidel.

June-September 2001. **Training period** in the laboratory of Immunology. Nottingham Trent University. Nottingham, UK. Title: “Identification of new tumor Antigens using SEREX”. Director: Prof. R. Rees. Supervisor: Dr. Amanda Miles.

### PUBLICATIONS

**Olivier Da Ines, Katja J. Franck, Birgit Geist, Ulrich Hammes, Gerhard Welzl and Anton R. Schäffner.** 2008. Differential roles of PIP2 aquaporins in *Arabidopsis thaliana*. (submitted to Plant Physiology).

**Aniela Sommer, Birgit Geist, Olivier Da Ines, Renate Gehwolf, Anton R. Schäffner, and Gerhard Obermeyer.** Ectopic expression of *Arabidopsis PIP2* aquaporins in lily pollen increases the plasma membrane water permeability of grain but not of tube protoplasts. (submitted to New Phytologist).
