ABSTRACT

Extravasation of neutrophils from postcapillary venules into inflamed tissue is a crucial step during the inflammatory response. Within this process, neutrophils migrate across the endothelium and subsequently need to penetrate the perivascular basement membrane. The precise regulation of both steps is not fully understood, yet. By using multiphoton intravital microscopy and immunofluorescence staining we identified mammalian sterile 20-like kinase 1 (MST1) as a key player for the migration of neutrophils through the perivascular basement membrane. Mst1 knock out neutrophils (Mst1^{-/-}) persist between the endothelium and the basement membrane of inflamed murine cremaster muscle venules and fail to migrate into inflamed tissue. Mst1^{-/-} neutrophils also fail to extravasate from gastric submucosal vessels in a murine Helicobacter pylori infection model. Mechanistically, impaired extravasation of Mst1^{-/-} neutrophils was accompanied by defective translocation of VLA-3, VLA-6, and neutrophil elastase from intracellular vesicles to the neutrophil surface, a requirement for neutrophils to penetrate the basement membrane. Taken together, our findings identify MST1 as a critical regulator of neutrophil transmigration and emphasize the importance of MST1-dependent vesicle trafficking for the recruitment process.

1 INTRODUCTION

In humans, neutrophils are the most abundant white blood cells in the circulation, the key cell type of the innate immune system. Neutrophils are the first line of defense; they are the first leukocytes to be recruited to the site of infection and are the major pathogen-fighting immune cells. It is crucial for them to extravasate from the blood vessel to the site of infection. Successfully transmigrated neutrophils recognize, phagocytose and consequently kill pathogens within tissue. They control local infections via various cytotoxic mechanisms, including reactive oxygen species (ROS) production, release of antimicrobial peptides and the release of neutrophil extracellular traps (NETs).

Neutrophil recruitment, activation and function needs to be tightly regulated as malfunction leads to diverse disorders. For example human leukocyte adhesion deficiencies (LAD) are severe immunodeficiencies leading to recurring bacterial and fungal infections due to inherited defects in selectin ligands (LADII), β2 integrins (LADI) or Kindlin3 (LADIII) and consequently profound defects in neutrophil recruitment (Schmidt et al., 2013), whereas an extensive or prolonged response results in tissue damage as observed in certain forms of vasculitis and autoimmune disease (Mayadas et al., 2014).

1.1 NEUTROPHIL RECRUITMENT

Recruitment of neutrophils from postcapillary venules to sites of inflammation is a fundamental process during the innate immune response. This process follows a well-defined cascade of events, including neutrophil tethering and rolling, firm adhesion, crawling, extravasation and migration into inflamed tissue (Nourshargh and Alon, 2014) (Figure 1.1).
Introduction

Figure 1.1 Neutrophil recruitment cascade
Schematic representation of the sequential steps of neutrophil recruitment from postcapillary venules into tissue. Neutrophil tethering and rolling, mediated via selectin and selectin ligand interaction, is followed by adhesion and intravascular crawling, which involves the β2 integrins LFA1 and Mac1. After finding the appropriate exit point neutrophils migrate through the endothelium via the paracellular or the transcellular route. Following transendothelial migration, neutrophils crawl at the abluminal side of the vessel, interacting with pericytes, and finally extravasate from low expression regions within the basement membrane. Adapted from (Vestweber, 2015)

1.1.1 Luminal interactions between neutrophils and the endothelium

Neutrophil recruitment is initiated by inflammatory mediators which induce changes in the surface expression of adhesion and activation molecules on endothelial cells. Depending on the time and stimulus, P-selectin, prestored in Weibel-Palade bodies, is upregulated within minutes, whereas de novo synthesized E-selectin can only be detected in sufficient quantities more than 90 min after stimulation. Circulating neutrophils, expressing P-selectin glycoprotein ligand 1 (PSGL1), E-selectin ligand 1 (ESL1), CD44 and L-selectin, interact with P-selectin and E-selectin on the endothelium initiating capture and rolling. E- and P-selectin bind to PSGL-1 and CD44 inducing talin dependent conformational changes in LFA-1 leading to slow rolling (McEver, 2015). Our group recently discovered a new pathway, where E-selectin binding to PSGL-1 leads to the release of MRP8/14, which in turn binds to TLR4 and induces MyD88- and Rap1-dependent activation of LFA-1 leading to slow rolling of neutrophils across inflamed endothelium (Pruenster et al., 2015). In addition to selectin ligands, chemoattractants on the endothelium induce integrin activation (Kolaczkowska and Kubes, 2013). Crucial chemokines for neutrophil activation are CXCL8 (also known as IL-8) in humans and CXCL1 (also known as Keratinocyte-derived chemokine, Kc and analogue to CXCL8 in humans), CXCL2 and CXCL5 in mice. These chemokines bind to
CXCR2 on neutrophils and activate β2 integrins via inside-out signaling. The β2 integrins, lymphocyte function-associated antigen 1 (LFA1; CD18/CD11a; αLβ2) and macrophage-1 antigen (Mac1; CD18/CD11b; αMβ2), change their conformation and increase their affinity to endothelial expressed intercellular adhesion molecule 1 (ICAM1) and ICAM2 leading to neutrophil adhesion to the endothelium. Upon selectin binding or chemokine stimulation, talin1 interacts with the cytoplasmic tail of β2 integrins inducing the intermediate affinity of LFA1 which promotes slow rolling (Lefort and Ley, 2012, Pruenster et al., 2015, McEver, 2015). Binding of both, kindlin3 and talin1, to the cytoplasmic tail of β2 lead then to high affinity conformation of LFA1 and firm arrest of neutrophils on the inflamed endothelium (Lefort et al., 2012) (Figure 1.2).
After firm arrest, neutrophils actively crawl along the endothelium scanning for an exit point, a process which is mostly dependent on ICAM1-Mac1 interactions (Phillipson et al., 2006). In addition, blocking ICAM-2 function in vivo alters the dynamics of crawling neutrophils to a stop-start profile and prolongs the time neutrophils remain at endothelial cell junctions before initiating transmigration (Halai et al., 2014).

At exit sites, endothelial cells extend ICAM-1 and VCAM-1 enriched membrane structures at their apical surface called ‘docking structures’ (Barreiro et al., 2002) or ‘transmigratory cups’ (Carman and Springer, 2004). These pseudopod-like apical membrane extensions surround transmigrating neutrophils. Neutrophil binding to endothelial ICAM-1 stimulates phosphorylation of cortactin, activation of RhoG and ICAM-1 clustering around transmigrating neutrophils (ICAM-1 ring like structures). Blocking RhoG activation inhibits ICAM-1 induced cortactin phosphorylation and neutrophil transendothelial migration (TEM) (Vestweber, 2015).

1.1.2 NEUTROPHIL TRANSMIGRATION

Neutrophils need to leave the vasculature in order to migrate to the site of injury or inflammation. Although most of the recruitment steps have been thoroughly studied in the past (Kolaczkowska and Kubes, 2013), the precise mechanism of neutrophil transmigration across venular walls remains elusive (Hallmann et al., 2015, Muller, 2015, Nourshargh and Alon, 2014, Rowe and Weiss, 2008, Sorokin, 2010, Vestweber, 2015). Neutrophils cross the endothelium within 2-5 min. This is followed by the penetration of the perivascular basement membrane (BM) and associated incomplete layer of pericytes, which takes 5-15 min (Kolaczkowska and Kubes, 2013). Transmigration through postcapillary venules can be divided into different steps: Transendothelial migration (TEM), abluminal crawling, followed by penetration through the perivascular BM and migration into the interstitial matrix to the site of inflammation (Nourshargh et al., 2010, Weninger et al., 2014, Nourshargh and Alon, 2014).
Transendothelial Migration

Intravascularly crawling neutrophils search for exit cues, which initiate TEM. Neutrophils breach the endothelial barrier regularly via the paracellular route (between adjacent endothelial cells, ~70-90%) and to a smaller extent via the less efficient transcellular route (through the endothelial cell), which can take 20-30 min (Kolaczkowska and Kubes, 2013). Adhesion molecules involved in neutrophil transmigration are listed in Table 1.1.

Table 1.1 Adhesion molecules involved in neutrophil extravasation from postcapillary venules

Successful TEM requires interaction of several adhesion molecules and receptors on neutrophils and/or endothelial cells: ICAM-1, ICAM-2, vascular cell adhesion protein 1 (VCAM-1) as well as the junctional proteins, including junctional adhesion molecules [e.g. JAM-A, JAM-B, JAM-C and endothelial cell-selective adhesion molecule 1 (ESAM-1)], platelet endothelial cell adhesion molecule (PECAM-1; also known as CD31), CD99 and CD99 antigen-like protein 2 (CD99L2) and poliovirus receptor (PVR) (Muller, 2015, Vestweber, 2015). These molecules participate in paracellular TEM, but not all of them are involved in transcellular migration. Furthermore, their roles vary between different leukocyte subsets, different organs, venules and inflammatory models (Kolaczkowska and Kubes, 2013, Muller, 2015, Nourshargh and Alon, 2014, Vestweber, 2015) (Table 1.1).

Comparing the effects of function blocking antibodies and knockout mice provided evidence for a sequential involvement of these molecules and receptors during neutrophil transmigration. In IL-1β stimulated murine cremaster muscles, neutrophils lacking JAM-A (genetic depletion) accumulate at endothelial cell junctions. Disruption of PECAM-1 (genetic depletion) arrests neutrophils between endothelial cells and the basement membrane (Woodfin et al., 2007, Bixel et al., 2010). Genetic depletion of ICAM-2 leads to the accumulation of neutrophils at the luminal surface above endothelial cell junctions (Woodfin et al., 2009). Interestingly, JAM-A, PECAM-1 and ICAM-2 display the same cytokine selectivity, as shown in studies where genetic disruption of JAM-A, PECAM-1 or ICAM-2 inhibited neutrophil transmigration in response to IL-1β, but not TNF-α. In contrast to IL-1β, TNF-α activates neutrophils, which may lead to TEM that can bypass the requirement for those receptors. Neutrophils lacking TNF-receptors require all three adhesion receptors to transmigrate in TNF-α stimulated postcapillary venules in the murine cremaster muscle (Woodfin et al., 2009). Blocking of CD99 or CD99L2 (functional blocking through specific antibodies) traps migrating neutrophils between endothelial cells and the basement membrane in postcapillary venules of IL-1β and TNF-α stimulated cremaster muscles, indicating its functional independence from the type of inflammatory stimulus (Bixel et al., 2010).
These studies established that neutrophil TEM is a sequential process, mediated by several cell surface receptors. So far, four positions are characterized: adhesion to the luminal surface above endothelial cell junctions (Position A); engaged between the endothelial junctions (Position B); detaching from the endothelium (Position C); between endothelial cells and the basement membrane (Position D) (Vestweber, 2015) (Figure 1.3).

The paracellular transmigration additionally requires the liberation of junctional intercellular protein bonds, such as those formed by vascular endothelial (VE)-cadherin. VE-cadherin is crucial for the stability of endothelial cell junctions. Vascular endothelial protein tyrosine phosphatase (VE-PTP) associates with VE-cadherin and supports its adhesive activity. Neutrophil-endothelial cell interaction and vascular permeability factors trigger the dissociation of VE-PTP from VE-cadherin, which is required for the positive regulation of this exit pathway. This implies that tyrosine phosphorylation of VE-cadherin and/or proteins in close proximity are required (Vestweber, 2015). Neutrophil bound ICAM-1 and VCAM-1 is indeed known to trigger tyrosine phosphorylation in the cytoplasmic domain of VE-cadherin. Dephosphorylation of Y731 of VE-cadherin is required for neutrophil recruitment in TNF-α as well as IL-1β stimulated cremaster muscle venules, whereas phosphorylation of Y685 is required for increasing the vascular permeability (Wessel et al., 2014, Vestweber, 2015).
TEM of neutrophils may be further supported by the lateral border recycling compartment (LBRC), a multi vesicular compartment inside of endothelial cells containing PECAM-1, CD99 and JAM-A (Mamdouh et al., 2009, Muller, 2015). LBRC vesicles are initially recruited via PECAM-1 to transmigrating neutrophils, followed by a second CD99-dependent wave, helping to accommodate the body of neutrophils within junctions (Mamdouh et al., 2003, Muller, 2015, Watson et al., 2015) (Figure 1.4).

**Figure 1.4 Sequential process of neutrophil transendothelial migration (TEM)**
TEM is a process mediated by neutrophils and endothelial cells: Stopping at preferential exit points; loosening of endothelial cell contacts; preventing plasma leakage; extending the membrane surface area via LBRCs; migration through the endothelial cleft; sealing of the endothelial cell junction; and dissociation from the endothelial cell. After TEM neutrophils need to transmigrate through the basement membrane. Adapted from (Vestweber, 2015)
Penetration of the basement membrane

Once neutrophils have migrated through the endothelial layer, they need to cross the underlying BM, a dense protein network embedded with pericytes, to enter inflamed tissues.

The perivascular BM consists of a dense (40-70 nm pore size) and heterogeneous network of collagen IV, nidogen1 and 2, perlecan and two specific laminin isoforms (isoform 511 and 411) (Hallmann et al., 2015, Sorokin, 2010, Rowe and Weiss, 2008, Weninger et al., 2014). The BM is crucial for the integrity of the blood vessel wall, and provides a tremendous barrier to transmigrating neutrophils.

Embedded in the BM pericytes reside and form an irregular network of cellular protrusions around the vessel, contributing to the composition of the basement membrane (Sorokin, 2010). Laminin 411 is ubiquitously expressed in perivascular BM of postcapillary venules. In contrast laminin 511 displays a patchy distribution with areas of low or no expression (Sixt et al., 2001, Wu et al., 2009, Voisin et al., 2010) and potentially also low expression of collagen IV (Wang et al., 2006, Proebstl et al., 2012). These 'low expression sites' (LER) localize at the gaps between pericytes (Sorokin, 2010, Voisin et al., 2010) and are the preferential sites for neutrophil extravasation (Wang et al., 2006). Laminin 411 deficient mice demonstrate a ubiquitous expression of laminin 511 in perivascular BM and show reduced neutrophil transmigration, indicating that laminin 511 has inhibitory effects on neutrophil migration (Kenne et al., 2010).

After TEM, neutrophils enter the subendothelial space and crawl along pericytes towards LERs, via pericyte expressed ICAM-1 and neutrophilic Mac-1 and LFA-1 (Proebstl et al., 2012, Ayres-Sander et al., 2013).

The mechanism through which neutrophils breach the perivascular BM is not fully understood yet (Rowe and Weiss, 2008). Neutrophils contain specific proteases, such as matrix metalloproteases (MMPs) and the serine protease, neutrophil elastase (NE), therefore it is tempting to argue that neutrophils 'cut' their way through the basement membrane, but neither genetic nor pharmacologic inhibitors could corroborate this (Kolaczkowska and Kubes, 2013). Maintenance of vascular integrity is indeed essential for tissue homeostasis, hence degradation of the basement membrane is unlikely and potentially contentious (Nourshargh and Alon, 2014, Rowe and Weiss, 2008, Hallmann et al., 2015).
Interestingly, neutrophils only penetrate the BM in the presence of an overlying endothelium, indicating that neutrophils are 'educated' by endothelial cells on how to cross the BM (Rowe and Weiss, 2008, Huber and Weiss, 1989). Furthermore, it was reported that LERs are transiently enlarged after neutrophil transmigration, probably through subtle disassembly and physical carriage of neutrophil bound BM-components (e.g. laminins) (Voisin et al., 2010, Wang et al., 2006).

After neutrophils have migrated through the endothelial layer, they are thought to interact with matrix components of the BM such as collagens and laminins via their surface molecules, β1 and β3 integrins. The use of function blocking antibodies and genetic deletion in in vivo studies have implicated several cell adhesion molecules, including the major laminin binding integrins on neutrophils, namely VLA-3 (α3β1, CD49c/CD29) (Hyun et al., 2012) and VLA-6 (α6β1, CD49f/CD29) (Dangerfield et al., 2005) and the junctional molecules ESAM-1, and PECAM-1 and CD99, expressed both by neutrophils and endothelial cells (Vestweber, 2015). These studies suggest that information obtained by migration across the endothelial cell monolayer primes neutrophils for the subsequent penetration of the endothelial BM.

VLA-3 was shown to be necessary for neutrophil extravasation in TNF-α and fMLP-induced transmigration in vivo (Hyun et al., 2012). Homophilic interactions between PECAM-1 on neutrophils and on endothelial cells induce the surface expression of VLA-6 on neutrophils enabling them to cross the basement membrane (Dangerfield et al., 2002). Using blocking antibodies suggest a role for VLA-6 in IL-1β, but not TNF-α dependent neutrophils extravasation (Dangerfield et al., 2005). Migration through the BM was described to be further accompanied by the surface expression of the serine protease NE (Wang et al., 2005), although experiments using NE deficient mice in vivo could not confirm a role of NE in the extravasation process (Young et al., 2007). Since VLA-3, VLA-6 and NE are stored in intracellular vesicles (Uriarte et al., 2008, Wang et al., 2005), they need to be translocated to the cell surface during transmigration.
1.2 Vesicle Trafficking in Neutrophils

Neutrophil immune function strongly depends on the capacity to synthesize and store pre-formed pro-inflammatory mediators in specialized intracellular vesicles (Sheshachalam et al., 2014). Defects result in severe immunodeficiency as seen in patients with neutrophil-specific granule deficiencies (Schaffer and Klein, 2013).

Mature neutrophils from the blood lack any proliferative capacity. Structurally, neutrophils possess a characteristic multi-lobed nucleus, very few mitochondria, a small Golgi apparatus, and a highly granular cytosol, that is packed with vesicles. In contrast to other cells, the protein content of neutrophil granules is not sorted, but sequentially formed during neutrophil differentiation (sequential synthesis model) (Le Cabec et al., 1996). Neutrophils consist of at least four types of granule structures: azurophilic (primary) granules, containing e.g. myeloperoxidases (MPO); specific (secondary) granules, containing e.g. lactoferrin; gelatinase (tertiary) granules, containing e.g. matrix metalloproteinases 9 (MMP9); and secretory vesicles (Table 1.2). Azurophilic as well as specific granules can be further subdivided due to their specific protein composition (Borregaard, 2010). Of note, in mature neutrophils secretory vesicles can also be formed de novo by the Golgi apparatus (Sheshachalam et al., 2014).

1.2.1 STIMULATION OF EXOCYTOSIS

In general, secretory vesicles and gelatinase granules can be rapidly transported to the plasma membrane (for example β2 integrins) upon moderate activation. A stronger activation of neutrophils is required to release azurophilic and specific granules (Kolaczkowska and Kubes, 2013, Mayadas et al., 2014). This hierarchy of granule release corresponds to the different roles of their secreted proteins during adhesion, migration, chemotaxis, phagocytosis and ROS production (Catz, 2014). During TEM, secretory vesicles are exocytosed to 100%, gelatinase granules to 38%, specific granules to 22% and azurophilic granules to only 7% (Rorvig et al., 2009, Sengelov et al., 1995).

Figure 1.5 Signaling cascade regulating neutrophil degranulation
Both, kinases and the fusion machinery regulate degranulation. Activated surface receptors trigger activation of kinases resulting in cytoskeletal remodeling. Docking of vesicles is regulated by interaction of Rab27 with Munc-13-4, which in turn interacts with SNARE leading to the fusion with the target membrane. Adopted from (Sheshachalam et al., 2014)
Due to high cytotoxicity, release of neutrophilic granules is strongly regulated by binary signals and involves on the one side adhesion-dependent mechanisms (β2-integrin or actin de-polymerization) and on the other ligation and activation of immune receptors (Sengelov et al., 1995). The Src kinases Fgr and Hck mediate both the adhesion-dependent signaling cascade and the immune receptor mediated activation (Mocsai et al., 1999). Current evidence favors the existence of an activation threshold, accomplished by binary signals, which induce degranulation or downstream pathways. This can induce an increase in intracellular Ca\(^{2+}\) and subsequently the hierarchical release of neutrophil granules in the order of secretory vesicles > gelatinase granules > specific granules > primary granules (Sengelov et al., 1993) (Figure 1.5).

1.2.2 VESICLE TRAFFICKING, DOCKING AND FUSION IN NEUTROPHILS

Granules and vesicles are transported to a target membrane (e.g. plasma membrane or phagosome) via actin remodeling and microtubule assembly through sequential actions of the core fusion machinery (Lacy and Eitzen, 2008, Sheshachalam et al., 2014, Toonen and Verhage, 2003).

Docking and fusion of granules and secretory vesicles to a target membrane are regulated by distinct core fusion proteins, involving the Rab and SNARE (soluble N-ethylmaleimide-sensitive factor attachment protein receptor) protein family. After Rab proteins tie vesicles to the membrane, SNARE proteins catalyze fusion (Lacy and Eitzen, 2008). Vesicle SNAREs (v-SNAREs) pair with target SNAREs (t-SNAREs) resulting in the fusion of vesicles with the target membrane. In neutrophils, vesicle-associated membrane protein 2 (VAMP-2) is mainly localized on secretory vesicles and gelatinase granules, whereas VAMP-7 is predominantly localized to azurophilic granules. Numerous proteins regulate the core fusion machinery and are important for SNARE complex formation (Sheshachalam et al., 2014) (Figure 1.6).
Figure 1.6 Vesicle trafficking to the target membrane
Vesicles are transported along cytoskeletal tracks. Rab-GTP on vesicles associates with motor proteins, directing the movement of the vesicle, and later with Rab effectors (tethering factors), bringing the vesicle in close proximity to the target membrane. Binding of v-SNAREs and t-SNAREs leads to the fusion of vesicles with the target membrane and the release of cargo proteins. Adapted and modified from (Vazquez-Martinez and Malagon, 2011)

1.2.3 Regulation of vesicle trafficking in neutrophils by Rab27a
The Rab27 GTPases regulate vesicle trafficking in neutrophils. This includes priming, tethering, docking and fusion to target membranes via interaction with multiple cell specific effector molecules. While Rab27 GTPases are expressed in a large variety of cell types and are involved in multiple steps, the expression of their effector proteins is more cell type specific and required to allow sequential interaction with Rab27 (Catz, 2013). Rab27a has emerged as a central regulator of many neutrophil functions, though its ability to regulate vesicle exocytosis (Catz, 2014). So far, two effector molecules, Synaptotagmin-like protein 1 (Slp1/JFC1) and Munc13-4, have been identified to interact with Rab27a in neutrophils (Brzezinska et al., 2008, Johnson et al., 2011b, Munafo et al., 2007, Pivot-Pajot et al., 2008). Rab27b, which is 72% homologous to Rab27a, binds to the same effector molecules as Rab27a and regulates several secretion mechanisms, although studies suggest different roles during azurophilic granules exocytosis in neutrophils (Brzezinska et al., 2008, Johnson et al., 2010).

Interestingly, out of more than 60 Rab GTPases expressed in humans, Rab27a is the only one associated with human disease. Patients with a genetic defect in Rab27a, a
disease called Griscelli syndrome type 2 (GS2), suffer from often fatal viral and bacterial infections, due to a severe immune deficiency, neutropenia, thrombocytopenia and uncontrolled T cell and macrophage activation (Harfi et al., 1992, Klein et al., 1994). Defects in Rab27a cause impaired function of cytotoxic T lymphocytes (CTL), natural killer cells (NK cell) and neutrophils (Munafo et al., 2007, Trambas and Griffiths, 2003).

**Rab27a-dependent trafficking of azurophilic granules**

Only ~20% of azurophilic granules are able to engage in exocytosis. This coincides with the percentage of azurophilic granules associated with Rab27a (Catz, 2013), but it is unclear whether only Rab27a positive azurophilic granules are mobilized to target membranes. Use of function blocking reagents or genetic deletion of Rab27a leads to impaired azurophilic granule exocytosis and decreased MPO plasma levels (Munafo et al., 2007, Johnson et al., 2010).

The Rab27a effector protein Slp1/JFC1 is expressed in neutrophils and was shown to bind and colocalize with Rab27a on azurophilic granules in close proximity to the plasma membrane (Catz, 2013). The loss of Slp1/JFC1 results in impaired release of azurophilic granules in response to fMLP in neutrophils (Brzezinska et al., 2008, Johnson et al., 2012). In addition, Slp1/JFC1 interacts with Gem-interacting protein (GMIP) regulating RhoA dependent actin remodeling facilitating docking and fusion of vesicles. Furthermore genetic deletion of Slp1/JFC1 or GMIP impairs exocytosis by trapping azurophilic granules within cortical actin, whereas inhibition of RhoA induces exocytosis via increased actin polymerization (Johnson et al., 2012) (Figure 1.7).
Another Rab27a effector protein, Munc13-4, also known as UNC13D, was first identified to associate with Rab27a dependent vesicles in platelets and CTLs. Later, it was discovered that Munch13-4 associates with gelatinase and azurophilic granules (colocalizing with MMP9) (Brzezinska et al., 2008, Pivot-Pajot et al., 2008). Function blocking antibodies or genetic deletion of Munc13-4 results in decreased MPO exocytosis and reduced granule docking at the plasma membrane (Johnson et al., 2011b). Munc13-4 links vesicles via two calcium sensitive lipid binding C2 domains (C2A and C2B) to the fusion machinery of SNAREs, regulating the docking of the vesicle to the plasma membrane (Brzezinska et al., 2008) (Figure 1.5). Another study recently showed that MST3 (STK24) and cerebral cavernous malformations 3 (CCM3) regulate exocytosis of azurophilic granules. Whereas MST3 inhibited Munc13-4 function, CCM3 antagonized MST3-mediated inhibition, providing additional regulation of degranulation (Zhang et al., 2013). Additionally, Munc13-4 controls phagosomal maturation by regulating the fusion of azurophilic granules and late endosomes to the phagosome, independent of Rab27a (Brzezinska et al., 2008, Johnson et al., 2011b, Monfregola et al., 2012).
Rab27a dependent trafficking of specific and gelatinase granules
In additional to its role in regulating azurophilic granule trafficking, Rab27a is also involved in specific and gelatinase granule trafficking as the blockade of Rab27a leads to impaired MMP9 release (Brzezinska et al., 2008). MMP9 is mostly stored in specific and gelatinase granules. After molecular interference with Rab27a, the upregulation of the specific granule marker CD66b is diminished, supporting the involvement of Rab27a in specific granule trafficking (Herrero-Turrion et al., 2008). Furthermore, it could be demonstrated that the Rab27a effector Munc13-4, but not Slp1/JFC1, is involved in gelatinase granule trafficking (Brzezinska et al., 2008, Pivot-Pajot et al., 2008).

Rab27a dependent trafficking of secretory vesicles
Secretory vesicles contain adhesion molecules, receptor and endocytic cargo proteins (Uriarte et al., 2008) and can be rapidly mobilized, even in response to weak stimulation. Mobilization of secretory vesicles containing Mac-1 or LFA-1, as well as α4β1 and α5β1 is not affected in Rab27a−/− or Munc13-4−/− neutrophils (Brzezinska et al., 2008, Johnson et al., 2010, Johnson et al., 2011a). In contrast, the surface expression of hyaluronan receptor CD44 is decreased in Rab27a−/− neutrophils, impairing neutrophil recruitment to the liver (Johnson et al., 2011a).
1.3 MAMMALIAN STERILE 20-LIKE KINASE (MST)

The Mammalian Sterile 20-like (MST) kinase family (Creasy and Chernoff, 1995), which is related to the Hippo kinase in *Drosophila melanogaster*, consists of five different proteins, which are conserved in all metazoans. These MST kinases can be divided into two subgroups, with the first group containing MST1 (also called STK4 or KRS2) and MST2 (also called STK3), and the second group containing MST3 (also called STK24), MST4 (also called STK26) and YSK1 (Yeast Sps1/Ste20-related kinase 1; also called STK25 or SOK1) (*Figure 1.8* demonstrates the relationship and *Table 1.3* gives an overview on the nomenclature of MST kinases) (Thompson and Sahai, 2015).

Despite millions of years of divergent evolution, MST family kinases exert similar functions across eukaryotes. MST family kinases influence cell proliferation, organ size, cell migration, cell polarity, and cell- and tissue homeostasis (Thompson and Sahai, 2015).

1.3.1 Mammalian sterile 20-like kinase 1/2 (MST1/2) subfamily

Cell division cycle 15 (Cdc15) in *S.cerevisiae* was the first MST kinase characterized (Hartwell et al., 1973, Thompson and Sahai, 2015) and turned out to be crucial for cell proliferation. Later, Hippo (Hpo) was discovered in *D.melanogaster* and identified to control tissue overgrowth by limiting cell proliferation (Halder and Johnson, 2011) (Figure 1.9). Both, Cdc15 and Hpo, are homologs of the mammalian MST1 and MST2.

Knockout of *Mst1* and *Mst2* (*Mst1*<sup>−/−</sup>*Mst2*<sup>−/−</sup>) in mice causes embryonic lethality, showing defects in placental development, vascular patterning, primitive hematopoiesis and regulation of cell proliferation and survival (Oh et al., 2009). *Mst1/2* conditional knockouts in the liver lead to tissue overgrowth and tumorigenesis (Lu et al., 2010, Zhou et al., 2009) (Figure 1.9). Conditional intestinal *Mst1/2* knockouts cause expansion of stem cell and progenitor cell compartments (Thompson and Sahai, 2015).

![Figure 1.9 Phenotypes of Hippo mutants in *D.melanogaster* and mice](image)

Scanning electron microscopy of WT (a) and hpo mutant *D.melanogaster* (b) (Halder and Johnson, 2011). Liver form 2 month old WT (c) and overgrown liver of 2 month old mice, where *Mst1/2* were conditionally deleted in the liver. Liver of 6 month old WT (e) and liver specific *Mst1*<sup>−/−</sup>*Mst2*<sup>−/−</sup> double knockout with overgrowth and foci of hepatocellular carcinoma in the later one (Lu et al., 2010). Adapted from (Johnson and Halder, 2014)
On a cellular level, hpo is known to control polarization of the F-actin cytoskeleton and cell migration. These functions are independent of the canonical Hippo pathway, arguing for a dual role of hpo and an additional non-canonical Hippo pathway (Lucas et al., 2013). The regulation of MST1/2 kinases is still unclear. Several mechanosensory systems are under discussion to directly or indirectly activate MST1/2 via cell (cytoskeleton) and tissue architecture (tissue forces) (Thompson and Sahai, 2015).

MST1 and MST2 share 88% similarity and 76% identity in amino acid (AA) sequence. Therefore, it is not surprising that Mst1 and Mst2 single knockout are viable, revealing that these two kinases act at least in part in a redundant fashion. Although Mst1/− mice are viable and develop normally, they display severe immunophenotypes (see below). In contrast, Mst2/− mice have no obvious phenotype (Oh et al., 2009).

1.3.2 Mammalian sterile 20-like kinase 1 (MST1)

MST1 is ubiquitously expressed with particularly high levels in lymphoid organs (Oh et al., 2009). Acting as a serine/threonine kinase MST1 has a N-terminal kinase domain, a coiled coil region, caspase 3 cleavage sites and a C-terminal SARAH domain. The SARAH domain is a highly conserved dimerization domain and important in regulating MST1, as it facilitates trans-autophosphorylation of the activation loop of MST1 through its ability to form antiparallel homodimers. MST1 can be cleaved by caspase 3 at 316 AA and 349 AA in response to apoptotic stimuli, separating the N-terminal kinase domain (37 kDa) and the C-terminal SARAH domain (18 kDa) (Thompson and Sahai, 2015) (Figure 1.10).

Figure 1.10 Schematic representation of MST1
STK4/ MST1 is a protein of 487 AA with a N-terminal kinase domain (30- 281 AA), a coiled coil region (290- 310 AA), caspase 3 cleavage sites (326, 349 AA) and a C-terminal SARAH domain (432- 480 AA) (Ren et al., 2009)
MST1 signaling can be divided into the canonical and non-canonical Hippo pathway. In the canonical pathway, activated MST1/2 stimulates Large tumor suppressor kinase (LATS) kinases, which phosphorylate and inactivate the transcription factor Yes-associated protein (YAP) and transcriptional co-activator with PDZ-binding motif (TAZ), restricting YAP and TAZ localization to the cytoplasm. Activated YAP and TAZ act as transcription factor and induce the expression of various genes controlling growth. Functions of MST1 other than growth and independent from LATS/ YAP/ TAZ are mediated via the non-canonical Hippo pathway and appear to be cell type specific. For example, genetic deletion of MST1 in T cells as well as activation of MST1 in HeLa or NIH-3T3 cells leads to an adhesion defect (Artemenko and Devreotes, 2013, Johnson and Halder, 2014) (Figure 1.11).

MST1/2 is expected to play important roles in cancer, given the importance in controlling cell proliferation. Although some mutations and fusions of MST1/2 have been discovered in some cancer types, those mutations did not appear in high frequency (Miyanaga et al., 2015).

![Figure 1.11 Canonical and non-canonical Hippo pathway](image)

On the left side the key steps of the canonical Hippo pathway are depicted, regulating growth. On the right side a simplified version of the non-canonical Hippo pathway in T cells is illustrated. Modified from (Artemenko and Devreotes, 2013).
During development and within the canonical pathway MST1/2 seem to have redundant roles. Interestingly, MST1 and MST2 do not act redundantly in immune cells, possibly reflecting different expression patterns. Loss of MST1 in humans leads to an immunodeficiency syndrome (Abdollahpour et al., 2012, Crequer et al., 2012, Nehme et al., 2012, Dang et al., 2016, Halacli et al., 2015). In addition, single nucleotide polymorphisms (SNPs) in MST1 are associated with colitis and Crohn’s disease (Nimmo et al., 2012, Waterman et al., 2011).

1.3.3 Function of MST1 in the immune system

The expression of murine MST1 is most abundant in lymphoid organs. MST1 is crucial for T cell selection in the thymus, adhesion, migration, growth and apoptosis (Dong et al., 2009, Katagiri et al., 2006, Katagiri et al., 2009, Mou et al., 2012, Zhou et al., 2008, Katagiri et al., 2011). Mst1−/− mice display a reduction in splenic white pulp, a decreased number of peripheral CD4+ and CD8+ T cells, B220+ B cells and absence of marginal zone B cells (Qin et al., 2013).

The role of MST1 in T cell development in the thymus

During development and maturation in the thymus, T cells undergo selection processes marked by the surface expression of CD4 and CD8: double negative (DN, CD4−CD8−) > double positive (DP, CD4+CD8+) > and single positive (SP, CD4+CD8− or CD4−CD8+). Throughout this selection, immature T cells undergo first a positive followed by a negative selection resulting in mature SP CD4+ and CD8+ T cells (Du et al., 2015). MST1 and MST2 expression can be detected in DP T cells and increases in SP T cells (Mou et al., 2012). In Mst1−/− mice the number of SP T cells in the thymus is increased (Dong et al., 2009, Katagiri et al., 2009), whereas the number of peripheral CD4+ and CD8+ T cells is strongly reduced (Dong et al., 2009, Katagiri et al., 2009, Zhou et al., 2008, Choi et al., 2009). It was shown that MST1 is important for negative selection, but not positive selection, most likely due to defects in LFA-1/ICAM-1 mediated adhesion, migration and antigen recognition (Ueda et al., 2012).

Of note, global deletion of Mst2 did not alter lymphocyte numbers, however additional elimination of Mst2 in the hematopoietic lineage (Mst1−/− Mst2fl/fl–VavCre
mouse) led to an aggravated phenotype compared to $Mst1^{-/-}$ mice, indicating that MST2 can partially compensate for the loss of MST1 (Mou et al., 2012, Du et al., 2014).

**MST1 regulates T cell apoptosis and survival**
The severe reduction in peripheral T cells in $Mst1^{-/-}$ mice is accompanied by a lower percentage of naïve T cells (CD62$^{\text{high}}$CD44$^{\text{low}}$) and a higher percentage of effector/memory T cells (CD62$^{\text{low}}$CD44$^{\text{high}}$) (Zhou et al., 2008, Du et al., 2014). This lymphopenic phenotype is more severe in $Mst1^{-/-}$ $Mst2^{fl/fl}$–$VavCre$ double knockout mice (Mou et al., 2012), and reflects the phenotype observed in human $STK4$ deficient patients (Abdollahpour et al., 2012, Nehme et al., 2012). The decrease of peripheral T cells is not only due to impaired egress from the thymus, but also due to enhanced cell death (Dong et al., 2009, Katagiri et al., 2009), indicating that MST1 is required for maintaining survival and inhibiting apoptosis, however the exact mechanism is still unclear given that results from different groups vary dramatically and are sometimes contradictory (Du et al., 2015).

**MST1 dependent T cell migration and homing**
MST1 is critical for lymphocyte trafficking by controlling the proper organization of LFA-1 at the leading edge (Du et al., 2015), a major adhesion molecule involved in T cell trafficking. The study by Katagiri et al. provided the first evidence, showing that knockdown of MST1 in T cells affected LFA-1 activation/ clustering, T cell polarization and adhesion in response to chemokine or TCR stimulation (Katagiri et al., 2006) and was later confirmed in $Mst1^{-/-}$ T cells (Katagiri et al., 2009, Zhou et al., 2008, Xu et al., 2014). Consistently, $Mst1^{-/-}$ mice display defective migration, antigen recognition (Ueda et al., 2012), impaired thymocyte egress (Mou et al., 2012, Dong et al., 2009, Katagiri et al., 2009) and decreased lymphocyte homing (Dong et al., 2009, Katagiri et al., 2009, Zhou et al., 2008).

Functional studies using $Mst1$-deficient mice showed that MST1 is involved in lymphocyte trafficking by controlling exocytosis and localization of lymphocyte function-associated antigen 1 (LFA-1; $\alpha L\beta2$) in the plasma membrane (Nishikimi et al., 2014). After chemokine stimulation, MST1 is activated and associates with the cytoplasmic tail of the $\alpha_L$ subunit via Rap1-RAPL (Katagiri et al., 2006, Katagiri et al., 2003).
Then, MST1 activates Rab13 by promoting phosphorylation DENND1C, the guanine nucleotide exchange factor (GEF) for Rab13. MST1 together with activated Rab13 leads to the translocation of LFA-1 containing vesicles along actin filaments in a myosin Va-dependent manner (Nishikimi et al., 2014). In addition, MST1 promotes polymerization of F-actin, by phosphorylating VASP, crucial for the Rab13-dependent mobilization of LFA-1 containing vesicles (Nishikimi et al., 2014, Du et al., 2015) (Figure 1.12). Mou et al. further demonstrated that MST1/2 are required for chemokine induced T cell migration and actin polarization by regulating Rho GTPase activation by enhancing Mob1 phosphorylation and its association with Dock8, a Rac1GEF (Mou et al., 2012).

Role of MST1 in B cells
The reduction of peripheral B cells in Mst1−/− mice is accompanied by a decreased number of splenic marginal zone B cells, reduced B cells adhesion and trafficking (Dong et al., 2009, Katagiri et al., 2009, Zhou et al., 2008). In contrast to T cells, little is known on the function of MST1 and MST2 in B cells. One study by Salojin et al. demonstrated that B cells from Mst1−/− mice have decreased responsiveness to B cell mitogen in vitro and defective IgE production in vivo (Salojin et al., 2014).

Role of MST1 in eosinophils
Both MST1 and MST2 are expressed in eosinophils. However only MST1 gets activated during apoptosis by caspase cleavage, suggesting a role for MST1 in the regulation of eosinophil apoptosis (De Souza et al., 2002). Interestingly, the same study reported no expression of MST1 in neutrophils (De Souza et al., 2002).
1.3.4 **HUMAN STK4 DEFICIENCY**

MST1 emerges as a critical regulator of lymphocyte function and autoimmunity. Recently, five independent groups identified mutations in the serine/threonine protein kinase 4 (*STK4*) in human patients causing a novel primary immunodeficiency, called *STK4* deficiency. This disorder is caused by an autosomal recessive nonsense mutation in *STK4*, which encodes for Mst1. So far, three patients form a consanguineous Iranian family (Abdollahpour et al., 2012), six patients form three consanguineous unrelated Turkish families (Halacli et al., 2015, Nehme et al., 2012), one patient from a consanguineous family of Senegalese origin living in France (Crequer et al., 2012) and three patients of a consanguineous family of unpublished origin (Dang et al., 2016) have been reported. Taken together, so far 16 patients from 6 consanguineous unrelated families were diagnosed with *STK4* deficiency, resulting from 6 different nonsense mutations in *STK4* gene (Abdollahpour et al., 2012, Crequer et al., 2012, Nehme et al., 2012, Dang et al., 2016, Halacli et al., 2015) (Table 1.4, Figure 1.13).

**Figure 1.13** Schematic representation of human mutations in *STK4*/*MST1*
Patients with STK4 deficiency suffer from T cell lymphopenia, with a low proportion of naïve T cells and a high proportion of effector T cells, and an impaired T cell response (Nehme et al., 2012). Additional neutropenia and heart malformations could be observed in some patients (Abdollahpour et al., 2012). Patients also display recurring bacterial, viral and fungal infections together with an autoimmune manifestation and their life expectancy is very short unless successfully transplanted. In particular, STK4 deficient patients frequently suffer from recurrent pulmonary infections, are susceptible to candidiasis, non-regressing cutaneous warts caused by multiple types of human papillomavirus infection and skin abscesses (Abdollahpour et al., 2012, Crequer et al., 2012, Nehme et al., 2012). Furthermore, different autoantibodies are detectable in these patients, indicative for autoimmune diseases (Abdollahpour et al., 2012, Nehme et al., 2012). Finally, T cells as well as neutrophils from STK4 deficient patients show increased susceptibility to apoptosis (Abdollahpour et al., 2012).

In contrast to STK4 deficient patients, no increased susceptibility to bacterial, viral and fungal infections have been reported for Mst1−/− mice, yet. However, similar to STK4 deficient patients, Mst1−/− mice are prone to autoimmune diseases (Du et al., 2014, Ueda et al., 2012). Several studies suggest, that the major cause of autoimmune disease in Mst1−/− mice is the impaired function of regulatory T cells (Tregs) in absence of MST1 (Du et al., 2014, Tomiyama et al., 2013).

While lymphopenia may explain a major part of the clinical manifestation. Impaired responses to acute infections imply an additional defect in myeloid cell function (Abdollahpour et al., 2012, Crequer et al., 2012, Nehme et al., 2012, Dang et al., 2016, Halacli et al., 2015).
Children suffering from a novel primary immunodeficiency disorder, caused by nonsense mutations in STK4, suffer from lymphopenia, recurring bacterial, viral and fungal infections and their life expectancy is very short unless successfully transplanted. Furthermore, the group of Prof. Dr. Christoph Klein (LMU, München) also reported intermitted neutropenia (Abdollahpour et al., 2012), which together with the impaired response to acute bacterial and fungal infections suggests an additional defect in myeloid cell function.

Until now, little is known about the function of MST1 in myeloid cells, especially in neutrophils. Therefore, in this study the function of MST1 in neutrophils during acute inflammation in humans and mice was elucidated, hypothesizing that the loss of MST1 leads to defective myeloid cell trafficking.

The specific aims of the thesis include:

- to identify potential defects in neutrophil rolling and slow rolling in the absence of MST1
- to uncover any impairment in neutrophil firm adhesion and neutrophil crawling in Mst1⁻/⁻ mice
- to reveal putative neutrophil transmigration defects in the absence of MST1
- to elucidate impaired interstitial migration in Mst1⁻/⁻ mice
3 MATERIALS

3.1 LABORATORY ANIMALS

*Mst1*\(^{-/-}\) mice were generated and provided by Dae Sik Lim, Biomedical Research Center, Korea Advanced Institute of Science and Technology, Daejon, Korea (Oh et al., 2009). *Lyz2*\(^{GFP}\) (Faust et al., 2000) were generously provided by Thomas Graf, Centre for Genomic Regulation, Barcelona, Spain. *Mst1*\(^{-/-}\) x *Lyz2*\(^{GFP}\) were created by crossbreeding. C57BL/6 wild type (WT) mice were obtained from Janvier Labs (Saint Berthevin, France). All mice were maintained and bred at the Walter Brendel Center for Experimental Medicine, Ludwig Maximilians Universität, Munich, Germany. Animal experiments were approved by Regierung von Oberbayern, Germany, AZ 55.2-1-54-2531-149/10 and AZ 55.2-1-54-2532-34/14.

### 3.2 Cell lines

1G11 murine lung endothelial cell line (Dong et al., 1997); generously provided by Annunciata Vecchi, Humanitas Research Hospital, Milan, Italy.

### 3.3 Buffers and solutions

#### Superfusion buffer

- 131.89 mM NaCl
- 4.68 mM KCl
- 2.66 mM CaCl₂
- 2.13 mM MgCl₂
- 18 mM NaHCO₃

#### HBSS buffer

- 1 mM MgCl₂: 0.038 g
- 1 mM CaCl₂: 0.044 g
- 0.1% glucose

#### HBSS++ buffer

- 100 ml HBSS: 250 ml
- 0.25% BSA: 625 mg
- 0.1% Glucose: 596 mg

adjust the pH to 7.4
Annexin binding buffer
- 10 mM Hepes/NaOH
- 140 mM NaCl
- 2.5 mM CaCl2
- adjust the pH to 7.4

1.5M Tris-HCl, pH 8.8
- 1 L
  - Tris base
  - adjust the pH to 8.8

0.5M Tris-HCl, pH 6.8
- 1 L
  - Tris base
  - adjust the pH to 6.8

TBS buffer (10x)
- 1 L
  - Tris base
  - NaCl
  - Adjust to pH 7.5

TBS-T buffer
- 1 L
  - 100 ml 10x TBS buffer
  - Tween-20
  - 1 ml

SDS Running buffer (10x)
- 1 L
  - Tris base
  - Glycine
  - SDS

Blotting buffer (10x)
- 1 L
  - Tris base
  - Glycine

To make 1 L of 1x blotting buffer
- 100 ml blotting buffer (10x)
- 25 ml Methanol (fresh)
- Add H2O to a final volume of 1 L
**modified RIPA lysis buffer**

- 150 mM NaCl
- 1% Triton X-100
- 0.5% sodium deoxycholate
- 50 mM Tris-HCl, pH 7.3
- 2 mM EDTA
- 1x protease inhibitor mixture [Roche]
- 1x phosphatase inhibitor cocktail 1+2 [Sigma-Aldrich]

**5x Laemmli sample Buffer**

- 1M Tris-HCl, pH 6.8
- 1% SDS
- 50% Glycerin
- β-Mercaptoethanol
- Bromphenol blue

50 ml

- 15 ml
- 5 g
- 25 ml
- 10 ml
- 125 mg

store at -20°C

**FACS buffer**

- 1% BSA in PBS

**Narcotic Ketamin/Xylazin**

- 125 mg kg$^{-1}$ Ketamin
- 25 mg kg$^{-1}$ Rompun 2% (Xylazin) in NaCl

**3.4 MEDIA**

**Medium for 1G11 murine endothelial cells**

- DMEM (low Glucose) 500 ml
- 1% non-essential amino acids
- 1 mM L-Glutamine
- 1 mM Na-pyruvate
- 100 µg/ml Heparin
- 20% FCS
- 1 mM Penicillin/ Streptavidin

4 METHODS

4.1 NEUTROPHIL RECRUITMENT IN VIVO

4.1.1 CONVENTIONAL INTRAVITAL MICROSCOPY OF THE MOUSE CREMASTER MUSCLE

Anesthetized mice (using 125 mg kg$^{-1}$ Ketamin and 25 mg kg$^{-1}$ Xylazin 2%) were intubated (plastic tube inner diameter (ID): 0.76 mm; outer diameter (OD): 1.22 mm) and a carotid artery catheter (plastic tube ID: 0.28 mm; OD: 0.61 mm) was placed to inject blocking antibodies and collect whole blood for analysis using ProCyte Dx (IDEXX Laboratories). The cremaster muscle was exteriorized and a superfusion buffer - preheated and saturated with 95% N$_2$ and 5% CO$_2$ was used to moisturize the tissue and reduce oxygen levels. Venules were recorded for at least 1 min by intravital microscopy (Olympus BX51WI microscope, water immersion objective 40x, 0.80 NA, Olympus; CCD camera, CF8/1, Kappa). Thereafter, rolling flux fraction (rolling cell min$^{-1}$ divided by all neutrophils passing the vessel min$^{-1}$), rolling velocity and neutrophil adhesion efficiency (number of adherent neutrophils mm$^{-2}$ divided by the systemic neutrophil count) determined, as described before (Pruenster et al., 2015). Postcapillary venules ranged from 20-40 μm in diameter. Blood flow velocity was measured using a dual photodiode connected to a digital on-line temporal intensity cross-correlation program (Circusoft Instrumentation, Hockessin, USA; originally developed by Wayland & Jonson 1967). Microvascular parameters (venular diameter, venular vessel segment length) were determined using Fiji software (Schindelin et al., 2012).

Trauma induced cremaster muscle model and CXCL1 induced adhesion

The trauma induced cremaster muscle model was used to observe leukocyte recruitment under mild inflammatory conditions in WT and $Mst1^{-/-}$ mice (Ley et al., 1995). Briefly, the cremaster muscle was exteriorized and superfused for 20 min before recording venules.

In a second step, a venule was recorded before CXCL1 (Kc) injection, whole blood was collected and 600 ng CXCL1 was injected i.v. through the carotid artery.
catheter. One minute after CXCL1 injection the same venule was recorded again for 1 min and the number of adherent neutrophils was compared.

**TNF-α induced cremaster muscle model**

Leukocyte recruitment in TNF-α stimulated mouse cremaster muscle venules was observed in WT and Mst1⁻/⁻ mice, as previously described (Frommhold et al., 2010). Briefly, 2 h after intrascrotal injection of TNF-α (500 ng mouse⁻¹) the cremaster muscle was exteriorized and rolling flux fraction (rolling cell min⁻¹ divided by all neutrophils passing the vessel min⁻¹), rolling velocity and neutrophil adhesion efficiency (number of adherent cells mm⁻² divided by the systemic neutrophil count) determined by intravital microscopy. Injection of anti-mouse E-selectin (clone 9A9, 30 µg, i.v.), anti- mouse P-selectin (RB40.34, 30 µg, i.v.), anti-mouse L-selectin (MEL14, 30 µg, i.v.), anti-mouse LFA-1 (TIB 217, M17/4.4.11.9, 100 µg i.p., one hour prior stimulation), anti-mouse Mac1 (TIB 218, M1/70.15.11.5HL, 100 µg i.p., one hour prior stimulation), and anti-mouse ICAM-1 (YN1/1.7.4, 100 µg i.p., one hour prior stimulation) were used to alter rolling and adhesive properties.

**4.1.2 Multi-photon intravital microscopy of the mouse cremaster muscle**

Extravasation of neutrophils into the inflamed mouse cremaster muscle of Lyz2GFP (Faust et al., 2000) and Lyz2GFP x Mst1⁻/⁻ mice was investigated by multi photon microscopy (Woodfin et al., 2011). Briefly, TNF-α (500 ng mouse⁻¹) and a rat anti-mouse PECAM-1 antibody labeled with Alexa Fluor 546 (clone 390; labeled ‘in house’ with monoclonal antibody labeling kit; 3 µg) were injected into the scrotum of mice. One hour later, the cremaster muscle was prepared for intravital multi photon microscopy. Z-stacks of postcapillary venules between 20-40 µm in diameter were captured using a TrimScope (LaVision Bio Tec (Rehberg et al., 2011), upgraded with Hamamatsu H7422A-40 high sensitivity GaAsP photomultipliers; Olympus XLUMPlanFl, 20x water immersion objective, 0.95 NA, 810 nm excitation, 390/80 for SHG signal, ultra-sensitive port (USP) 525/50 for GFP, 580/60 for PECAM1-Alexa Fluor 546 detection). Images were acquired by sequential scans at a resolution of 966 x 966 pixels, corresponding to 300 x 300 µm. Stacks of images with a step size of 4 µm were acquired at intervals of 30 seconds. After acquisition, sequences of z-stacks were processed and analyzed using
Imaris 7 and Fiji software. Transmigration time was defined from the point neutrophils started to transmigrate (excluding intraluminal crawling) until they completely detached from the abluminal vascular wall.

**Laser induced injury using multi-photon intravital microscopy**

Neutrophil swarming to the site of injury was observed in Lyz2GFP and Lyz2GFP x Mst1/- mice. Four h after intrascrotal injection of TNF-α and one hour after anti-mouse PECAM1 Alexa Fluor 546 antibody intrascrotal injection, a laser injury was induced in the cremaster muscle using high laser power by scanning an area of 50 x 50 µm 121 times in the center of 500 x 500µm. Images were acquired for 30 min as described above. The GFP intensity, which is proportional to the number of neutrophils at the site of injury, was analyzed using Fiji software.

### 4.1.3 TNF-α INDUCED NEUTROPHIL EXTRAVASATION INTO THE PERITONEAL CAVITY

WT and Mst1/- mice were intraperitoneally injected with NaCl (control) or TNF-α (rmTNF-α, 1 µg mouse⁻¹). Mice were sacrificed 2 h later and peritoneal lavage performed using 5 ml ice-cold PBS. Cells were collected and stained with a rat anti-mouse Ly6G Pacific Blue antibody (1A8). Number of extravasated neutrophils was measured by using a Beckman Coulter Gallios™ flow cytometer with Flow-Count™ Fluorospheres and analyzed using Kaluza® Flow Analysis Software.

### 4.2 FLOW CHAMBER ASSAYS

#### 4.2.1 Murine ex vivo flow chamber system

To investigate adhesion under flow conditions we used a previously described flow chamber system (Yang et al., 2012). Glass capillaries (Rect.Boro Capillaries 0.04 x 0.40 mm ID VitroCom, Mountain Lakes, USA) were coated overnight with combinations of E-selectin (CD62E, rmE-selectin Fc chimera, 20 µg ml⁻¹), ICAM-1 (rmICAM-1 Fc chimera, 15 µg ml⁻¹) and CXCL1 (rmCXCL1, 15 µg ml⁻¹). Flow chambers were auto perfused with whole blood from WT or Mst1/- mice via a carotid artery catheter with a shear stress of 2.7 dyne cm⁻². One representative field was recorded (Olympus BX51WI microscope...
with a CCD camera CF8/1, Kappa, Germany; water immersion objective x20, 0.95 NA, Olympus). Number of adherent cells was determined using Fiji software.

4.2.2 LFA-1 CLUSTERING UNDER FLOW CONDITIONS

In order to investigate LFA-1 clustering during neutrophil adhesion under flow conditions, flow chambers were perfused (2 µl min⁻¹) with whole blood from WT or Mst1⁻/⁻ mice, incubated with rat anti-mouse LFA-1 Alexa Fluor 546 antibody (2D7, labeled ‘in house’ with monoclonal antibody labeling kit; 2.5 µg) for 10 min. Adherent cells were imaged using confocal microscopy (Leica System SP5, 63x, 1.4 NA oil objective, xyzt-series).

4.2.3 HUMAN FLOW CHAMBER SYSTEM

In order to investigate adhesion of human neutrophils under flow conditions we used a previously described flow chamber system (Nussbaum et al., 2013). Glass capillaries (Rect.Boro Capillaries 0.2 x 2 mm ID VitroCom, Mountain Lakes, USA) were coated overnight with combinations of E-selectin (rhCD62E Fc chimera, 5 µg ml⁻¹), ICAM-1 (rhICAM-1 Fc chimera, 4 µg ml⁻¹) and CXCL8 (interleukin8, IL-8; rhCXCL8, 5 µg ml⁻¹). Whole blood was isolated from two patients with STK4 deficiency and their heterozygous parents in Hannover, Germany and sent to Munich for analysis. Flow chambers were perfused with Polymorphoprep™ purified blood neutrophils (2 x 10⁶ ml⁻¹) from parents (STK4⁺/⁻) or STK4⁻/⁻ patients using a high precision pump with a shear rate of 2 dyne cm⁻². One representative field of view was recorded (Olympus BX51WI microscope with a CCD camera CF8/1, Kappa, Germany; water immersion objective 20x, 0.95 NA, Olympus). Number of adherent cells was determined. Experiments were approved by the ethical committee, LMU, Germany, AZ 66-14.
4.3 FLUORESCENCE ACTIVATED CELL SORTING (FACS)

4.3.1 NEUTROPHIL AND MONOCYTE DIFFERENTIATION

To differentiate between neutrophils and monocytes, antibodies against CD45 and CD11b were used to gate CD45\(^{\text{high}}\), CD11b\(^{+}\) myeloid cells. To further differentiate antibodies against CD115 and Gr-1 were used to identify neutrophils (Gr-1\(^{\text{high}}\), CD115\(^{-}\)), inflammatory (Gr-1\(^{\text{high}}\), CD115\(^{+}\)) and non-inflammatory monocytes (Gr-1\(^{\text{low}}\), CD115\(^{+}\)).

4.3.2 SURFACE EXPRESSION ON NEUTROPHILS

Surface expression of αL (LFA-1, CD11a, M17/4), αM (Mac-1, CD11b, M1/70), CXCR2 (CD182, 242216), CD44 (CD44, IM7), PSGL1 (CD162, 2PH1) und L-selectin (CD62L, MEL-14) of bone marrow and blood derived Ly6G\(^{+}\) (Ly6G, 1A8) neutrophils from WT and Mst1\(^{-/-}\) mice was compared using a Beckman Coulter Gallios™ flow cytometer and analyzed using Kaluza® Flow Analysis Software (Beckman Coulter).

4.3.3 SELECTIN BINDING TO NEUTROPHILS

E- and P- selectin binding was performed as described previously (Borsig et al., 2002). Briefly, whole blood was isolated from WT and Mst1\(^{-/-}\) mice and incubated with an Fc-blocking antibody for 15 min at 4°C. Meanwhile selectin-chimeras were pre-complexed by incubating P- or E-selectin hFc chimera (3.6 µg) with goat anti-human Fc gamma-biotin in 100µl HBSS buffer for 20 min at room temperature. Cells were incubated with pre-complexed selectin-chimera with or without EDTA (10mM) for 50 min at 4°C. EDTA served as a negative control due to its ability to form complexes with Ca\(^{2+}\) and Mg\(^{2+}\), both cations are required for selectin binding. Cells were fixed (FACS Lysing Solution), stained with streptavidin PE-Cy5 and rat anti-mouse Ly6G-Pacific Blue antibody (1A8) and measured using a Beckman Coulter Gallios™ flow cytometer. For the analysis, Kaluza® Flow Analysis Software was used.
4.3.4 SOLUBLE ICAM-1 BINDING TO NEUTROPHILS

A soluble ICAM-1 binding assay was performed as described previously (Lefort et al., 2012). Briefly, bone marrow neutrophils were isolated from WT and Mst1−/− mice using a Percoll gradient. Cells were suspended in complete HBSS++ buffer. Cells were stimulated with 100 ng ml⁻¹ CXCL1 or an equal volume of HBSS++ buffer, in the presence of ICAM-1 (rmICAM-1 hFc chimera, 20µg ml⁻¹), goat anti-human Fc gamma-biotin and Streptavadin – PerCP-Cy5.5 for 3 min at 37°C. Cells were fixed, stained with rat anti-mouse Ly6G-Pacific Blue antibody (1A8) and measured using a Beckman Coulter Gallios™ flow cytometer. For the analysis, Kaluza® Flow Analysis Software was used.

4.3.5 PHAGOCYTOSIS

Phagocytic capacity of neutrophils was evaluated using pHrodo™ E.coli BioParticles Phagocytosis Kit according to manufacturer. Briefly, whole blood from WT and Mst1−/− mice was incubated with pHrodo particles for 15 min at 4°C or 37°C. A rat anti-mouse Gr1-eFluor 405 antibody was used to identify neutrophils (Gr1hi). Using the pHrodo™ dye fluorescence intensity of WT and Mst1−/− neutrophils was evaluated by using a Beckman Coulter Gallios™ flow cytometer.

4.3.6 NEUTROPHIL VIABILITY

Viability and apoptosis rate of neutrophils was evaluated using T-MRE (tetramethylrhodamine) and TO-PRO3, respectively. The positively charged dye, T-MRE accumulates in active mitochondria due to their relative negative charge. Depolarized or inactive mitochondria with decreased membrane potential fail to gather T-MRE, making it suitable to indicate live cells (Barteneva et al., 2014). TO-PRO3 is taken up by apoptotic cells via pannexin 1 channels (Poon et al., 2014). Briefly, isolated neutrophils were cultured in HBSS++ buffer for 0, 24, 48 and 72 h. Afterwards cells were stained with T-MRE, TO-PRO3 and anti-Ly6G- PB antibody and measured using a Beckman Coulter Gallios™ flow cytometer.
4.3.7 **NUMBER AND VIABILITY OF NEUTROPHILS WITHIN THE CREMASTER MUSCLE**

In order to evaluate the total number of neutrophils within the whole cremaster muscle, TNF-α (500 ng mouse⁻¹) was injected into the scrotum of WT and Mst1⁻/⁻ mice. Two hours later, the cremaster muscle was exteriorized, dissected and digested with Liberase (0.25 mg ml⁻¹) for 1 h at 37°C. Cells were stained with rat anti-mouse Ly6G PB antibody (1A8), T-MRE and TO-PRO3. The number of neutrophils and the viability was measured by using a Beckman Coulter Gallios™ flow cytometer with Flow-Count™ Fluorospheres and analyzed using Kaluza® Flow Analysis Software.

4.4 **NEUTROPHIL ISOLATION**

4.4.1 **MURINE NEUTROPHIL ISOLATION**

For murine neutrophil isolation either percoll density gradient centrifugation was performed or EasySep mouse neutrophil enrichment Kit was used according to the manufacturer (StemCell).

**Isolation of murine neutrophils using percoll density gradient centrifugation**

The principle of percoll gradient centrifugation was used to separate murine neutrophils. Briefly, two layers of percoll - lower layer with a density of 1.11 g ml⁻¹ and an intermediate layer with a density of 1.08 g ml⁻¹ – are carefully applied. Thereafter, diluted whole blood or bone marrow was applied to the top. After 30 min centrifugation at 1000 g without break, the second interphase containing enriched neutrophils was carefully transferred.

4.4.2 **HUMAN NEUTROPHIL ISOLATION**

To isolate human neutrophils, venous whole blood was collected using syringes (40 unit heparin ml⁻¹). Whole blood was carefully applied on top of a layer of Polymorphoprep™. After 30 min centrifugation at 500 g without break, the interphase containing enriched neutrophils was carefully transferred.
4.5 IMMUNOFLUORESCENCE

4.5.1 CREMASTER WHOLE MOUNT STAINING

TNF-α (500 ng mouse⁻¹) was applied to the scrotum of WT and Mst1⁻/⁻ mice. After 2 h the mouse cremaster muscle was dissected and fixed with 4% PFA for 1 h, permeabilized and blocked for 2 h in 0.5% Triton X-100/2% ovalbumine/PBS. Thereafter, the cremaster was incubated with rat anti-mouse laminin α5 antibody 4G6 (Sorokin et al., 1997), rabbit anti-mouse ESAM1 antibody (Wegmann et al., 2006) and goat anti-mouse MRP14 antibody (S100a9) overnight in 2% ovalbumine/PBS at room temperature (RT). After labeling with secondary antibodies (donkey anti-rat Alexa Fluor 488, donkey anti-goat Alexa Fluor 568, donkey anti-rabbit Alexa Fluor 647) in 1% ovalbumine/PBS for 5 h at RT, the tissue was embedded on glass slides in PermaFluor Mounting Medium under cover slips. In order to analyze neutrophil extravasation, z-stack images of vessels, with a length of over 150 µm without branching and an average diameter of 20-40 µm, were taken using confocal microscope (Zeiss LSM 780, LSM 510). Neutrophils, which appeared within 50 µm around the vessel segment were counted using Imaris software.

4.5.2 MOBILIZATION OF VLA-3, VLA-6, NE, MST1 AND RAB27A IN NEUTROPHILS

Mobilization of α3 (VLA-3, CD49c), α6 (VLA-3, CD49f) and neutrophil elastase (NE) on PECAM-1, ICAM-1 and CXCL1 coated wells was performed as previously described (Wang et al., 2005). Briefly, µ-Slide 8 well chambers were coated with either 2% BSA (control) or a combination of PECAM-1 (2 µg ml⁻¹), ICAM-1 (8 µg ml⁻¹) and CXCL1 (10 µg ml⁻¹) overnight at 4 °C. Bone marrow neutrophils from WT and Mst1⁻/⁻ mice were isolated using a Percoll gradient and incubated on coated wells for 30 min at 37 °C. Cells were fixed with 4% PFA for 15 min at RT, blocked and permeabilized with PBS/0.1% Triton X-100/2% BSA for 1 h at RT. Cells were incubated with the primary antibodies at 4 °C overnight, in the first set of experiments, cells were incubated with a rabbit anti-mouse NE antibody (polyclonal), a mouse anti-mouse VLA-3 antibody (42/CD49c) and rat anti-mouse VLA-6 Biotin conjugated antibody (GoH3) overnight at 4 °C.

In a second set of experiments, sheep anti-mouse Rab27a antibody, rabbit anti-mouse MST1 antibody (polyclonal) and rat anti-mouse VLA-6 antibody (GoH3) or sheep
anti-mouse Rab27a antibody, a rabbit anti-mouse NE antibody (polyclonal) and a rat anti-mouse VLA-6 antibody (GoH3) was used. Primary antibodies were detected using goat anti-mouse Alexa Fluor® 488, goat anti-rabbit Alexa Fluor® 546, Streptavidin Alexa Fluor® 647, donkey anti-sheep Alexa Fluor® 488 and goat anti-rat Alexa Fluor® 647, respectively. Cells were incubated for 1 h at room temperature. Finally, cells were embedded in PermaFluor and imaged by confocal microscopy (Leica System SP5, 63x, 1.4 NA oil objective) and analyzed using Fiji software.

4.5.3 In Vivo NE Activity Assay

NE680FAST (4 nmols per mouse) was injected i.v. One h later TNF-α (500 ng mouse⁻¹) was applied to the scrotum of WT and Mst1⁻/⁻ mice. Two h later, the mouse cremaster muscle was dissected and fixed with 4% PFA for 1 h, permeabilized and blocked for 2 h in 0.5% Triton X-100/ 2% ovalbumine /PBS. Thereafter, the cremaster was incubated with rat anti- mouse PECAM-1 antibody labeled with Alexa Fluor 488 (MEC13.3) overnight in 2% BSA/ PBS at room temperature (RT). As a control, only TNF-α (500 ng mouse⁻¹) was applied to the scrotum of WT and Mst1⁻/⁻ mice and stained using rabbit anti-mouse MRP14 antibody (gift of Thomas Vogl, University Münster, Germany). The MRP14 antibody was detected with a goat anti-rabbit Alexa Fluor® 546 antibody (Molecular Probes/ Invitrogen). Afterwards, tissues were embedded on glass slides in PermaFluor under cover slips. Finally, whole cremaster were imaged by confocal microscopy (Leica System SP5, 40x, 1.4 NA oil objective) and analyzed using Fiji and Imaris software.

4.6 Western Blotting

Murine neutrophils from WT and Mst1⁻/⁻ mice were isolated from bone marrow using EasySep™ mouse neutrophil enrichment kit. Cells were incubated in lysis buffer, homogenized in Laemmli sample buffer and boiled for 5 min at 95°C. Proteins were resolved by SDS–polyacrylamide gel electrophoresis (SDS–PAGE) gels and then electrophoretically transferred from the gels onto PVDF membranes. Membranes were incubated with rabbit anti-mouse MST1 antibody (Upstate), rabbit anti-mouse MST2
antibody, rabbit anti-mouse NE antibody, mouse anti-mouse VLA-3 antibody (42/CD49c), rabbit anti-mouse VLA-6 antibody, sheep anti-mouse Rab27a or mouse anti-mouse GAPDH antibody and subsequently labeled with goat anti-mouse HRP, goat anti-rabbit HRP or donkey anti-sheep HRP. Bound antibodies were detected using enhanced chemiluminescence using Hamamatsu ORCA system.

4.7 CELL CULTURE

4.7.1 TRANSWELL ASSAYS

Murine neutrophils were isolated from bone marrow using EasySep™ mouse neutrophil enrichment kit. Complete HBSS buffer, 10 ng ml⁻¹ CXCL1 or 100 ng ml⁻¹ CXCL1 was applied to the lower compartments of the transwell system (5 µm pore size). Isolated neutrophils were applied to the upper compartment (5x10⁵ cells per well) and allowed to migrate for 45 min at 37°C. Cells were collected from the lower chamber and stained with a rat anti-mouse Ly6G Pacific Blue antibody (1A8). Number of transmigrated neutrophils was measured by using a Beckman Coulter Gallios™ flow cytometer with Flow-Count™ Fluorospheres and analyzed using Kaluza® Flow Analysis Software.

Transwell assay with filters coated with murine laminin

In a second set of experiments, we performed transmigration assays with additional coating of the membrane as described before (Wang et al., 2005). Briefly, the membrane of the transwell system (3 µm pore size) was coated with laminin 1 (15 µg ml⁻¹) or 2% BSA as a control at 4 °C overnight. Afterwards, laminin was additionally coated with a combination of PECAM-1 (2 µg ml⁻¹) and ICAM-1 (8 µg ml⁻¹) for 2 h at 37 °C. Either complete HBSS buffer alone or with 1 ng ml⁻¹ CXCL1 was added to the lower compartments. Isolated bone-marrow neutrophils (2x10⁵ cells per well) were suspended in complete HBSS buffer, added to the upper compartment and allowed to migrate for 3 h at 37 °C. Cells were collected from the lower chamber and stained with a rat anti-mouse Ly6G Pacific Blue antibody (1A8). Number of transmigrated neutrophils was evaluated by using a Beckman a Coulter Gallios™ flow cytometer with Flow-Count™ Fluorospheres.
Transwell assay with filters coated with murine endothelial cells

In a third set of experiments, murine endothelial 1G11 cells (kindly provided by Annunciata Vecchi) were seeded on transwell inserts (5 µm pore size) coated with 2% gelatin and cultured until a monolayer has formed (on average overnight). Either complete HBSS buffer alone or with 100 ng ml⁻¹ CXCL1 was added to the lower compartments. After 30 minutes of equilibration, isolated bone marrow neutrophils (2×10⁵ cells per well) were added to the upper compartment and allowed to migrate for 1 h at 37 °C. Numbers of transmigrated cells were evaluated using Ly6G-pacific blue and Flow-Count™ Fluorospheres with flow cytometry.

4.7.2 3D COLLAGEN MIGRATION

3D Chemotaxis was performed according to the manufacturer’s instructions. Briefly, bone marrow neutrophils from WT and Mst1⁻/⁻ mice were isolated using a Percoll gradient and 3×10⁵ cells were seeded together with Collagen I into a channel of Ibidi µ-Slides Chemotaxis³D. After 5 min of incubation at 37 °C, the reservoirs were filled with either complete HBSS buffer alone or with CXCL1 (100 ng ml⁻¹) or fMLP (10 µM). Images were acquired every 14 sec for 30 min at 37 °C using an Axiovert 200M microscope. Images were analyzed using Fiji software.

4.8 STATISTICAL ANALYSES

All data were analyzed and plotted using Graph Pad Prism 6 Software. For pairwise comparison of experimental groups a paired t-test, unpaired t-test or Mann-Whitney test was performed. For multiple comparisons, a two way analysis of variance (ANOVA) was used with either Sidak’s multiple comparisons test or Tukey’s multiple comparisons test (comparison of all experimental groups against each other). A p-value < 0.05 was considered as statistically significant.
5 RESULTS

5.1 CHARACTERIZING NEUTROPHILS OF MST1 KNOCK OUT MICE

In the past, conflicting results on the expression of MST1 in mouse neutrophils were published (De Souza et al., 2002). Therefore, we first confirmed the expression of MST1 in neutrophils from wild type (WT) and the absence of MST1 in Mst1−/− neutrophils (Figure 5.1a). In addition, the expression of MST2 was tested and no MST2 expression could be detected neither in WT nor Mst1−/− neutrophils (Figure 5.1b). GAPDH served as a loading control.

![Image of protein levels](image)

**Figure 5.1 Protein levels of MST1 and MST2 in neutrophils**
(a) MST1 and (b) MST2 protein levels are shown from neutrophils of WT and Mst1−/− mice. GAPDH served as loading control. EGF-stimulated A431 cell lysate was used as control for MST2 expression (n=3).

Next, peripheral blood cell counts were determined and, as previously reported (Choi et al., 2009), a decreased number of lymphocytes found in Mst1−/− mice compared to WT mice (Figure 5.2). Neutrophil counts were not significantly altered in Mst1−/− mice (881 ± 204 neutrophils µl⁻¹, mean ± SEM) compared to WT mice (669 ± 103 neutrophils µl⁻¹, mean ± SEM).
5.1.1 Viability and Apoptosis of WT and Mst1\(^{−/−}\) Neutrophils

Numerous publications demonstrated that MST1 regulates apoptosis and proliferation in a cell type specific manner (Johnson and Halder, 2014). To determine whether MST1 has an effect on the survival of neutrophils, isolated bone marrow neutrophils of WT and Mst1\(^{−/−}\) mice were cultured for 0, 24, 48 and 72 h. Neutrophils were measured by flow cytometry using T-MRE and TO-PRO3 to determine viability and apoptosis, respectively. As illustrated in Figure 5.3, the absence of MST1 had no effect on the viability of murine neutrophils in vitro.

![Figure 5.2 Differential blood counts of WT and Mst1\(^{−/−}\) mice](image)

**Figure 5.2 Differential blood counts of WT and Mst1\(^{−/−}\) mice**

Differential blood counts of WT (black circles, n= 20) and Mst1\(^{−/−}\) mice (grey circles, n= 14) (scatter blots with mean, *** p < 0.001, 2way ANOVA, Sidak’s multiple comparisons test).

![Figure 5.3 Viability and apoptosis of WT and Mst1\(^{−/−}\) neutrophils over time](image)

**Figure 5.3 Viability and apoptosis of WT and Mst1\(^{−/−}\) neutrophils over time**

Isolated neutrophils from WT (black circles) and Mst1\(^{−/−}\) mice (grey circles) were cultured for indicated times, stained with Ly6G, T-MRE and TO-PRO3 to quantify (a) viable (TO-PRO3\(^{−}\) T-MRE\(^{+}\)) and (b) apoptotic neutrophils (TO-PRO3\(^{+}\) T-MRE\(^{−}\)) (n=3, mean ± SEM).
5.2 MST1 IS DISPENSABLE FOR NEUTROPHIL ROLLING AND ADHESION IN HUMANS AND MICE

Previous studies have shown that MST1 is crucial for T-cell adhesion in vitro (Katagiri et al., 2006) and in vivo (Katagiri et al., 2009) by regulating LFA-1 localization on the T-cell surface (Nishikimi et al., 2014). Therefore, we compared leukocyte rolling and adhesion properties in vivo and in vitro between WT and Mst1−/− mice, both processes are affected by LFA-1 activity.

5.2.1 NEUTROPHIL ROLLING AND ADHESION IN MST1−/− MICE IN VIVO

To test whether the absence of MST1 influences neutrophil recruitment in vivo, rolling and adhesive properties of neutrophils were compared in trauma and TNF-α stimulated cremaster muscle venules of WT and Mst1−/− mice using conventional intravital microscopy.

Trauma induced cremaster muscle model

In this model mild trauma is caused by surgical preparation and exteriorization of the mouse cremaster muscle. Within minutes after exteriorization P-selectin is mobilized from Weibel-Palade bodies within the endothelial cell to the endothelial surface (Ley et al., 1995, Mayadas et al., 1993) leading to P-selectin dependent leukocyte rolling. The model the expression of E-selectin is absent or very low (Ley et al., 1995). Firm leukocyte adhesion is mostly mediated via LFA-1 and Mac-1 interacting with ICAM-1 and RAGE, respectively (Frommhold et al., 2010, Jung and Ley, 1997). Neutrophil rolling (Figure 5.4a), rolling velocity (Figure 5.4b) and neutrophil adhesion (Figure 5.4c) was comparable in trauma stimulated cremaster muscle venules between WT and Mst1−/− mice.
Figure 5.4 Neutrophil rolling and adhesion in the trauma stimulated cremaster muscles of WT and \textit{Mst1}⁻/⁻ mice
\textbf{(a)} Neutrophil rolling (rolling neutrophil min⁻¹ mm⁻¹), \textbf{(b)} cumulative distribution of neutrophil rolling velocities and \textbf{(c)} neutrophil adhesion (adherent neutrophil mm⁻²) in cremaster muscle venules was compared between WT (black circles) and \textit{Mst1}⁻/⁻ mice (grey circles) 20 to 40 min after trauma induction (n = 5, scatter blots with mean, n.s., unpaired t-test).

Next, LFA-1 dependent neutrophil adhesion was investigated by intravenous (i.v.) injection of CXCL1, which in turn activates LFA-1 via integrin inside-out signaling, leading to the arrest of neutrophils (Smith et al., 2004, Frommhold et al., 2008). To do this, one vessel was recorded before and 1 min after i.v. injection of 600 ng CXCL1. Neutrophil rolling (Figure 5.5a) and neutrophil adhesion (Figure 5.5b) before and after CXCL1 injection was compared between WT and \textit{Mst1}⁻/⁻ mice. The reduction in neutrophil rolling and the increase in neutrophil adhesion due to LFA-1 activation after CXCL1 injection was similar in WT and \textit{Mst1}⁻/⁻ mice.

**TNF-α stimulated cremaster muscle model**

Next, the TNF-α stimulated cremaster muscle model was used as a model of strong inflammation. TNF-α treatment leads to the expression of P- and E-selectin on the surface of the venular endothelium (Jung and Ley, 1997). This coincides with the induction of slow neutrophil rolling in these microvessels. The expression of ICAM-1 and VCAM-1 is increased, which corresponds to a high number of adherent neutrophils and neutrophil extravasation. No difference could be observed in rolling flux fraction (Figure 5.6a), rolling velocity (Figure 5.6b) or neutrophil adhesion efficiency between WT and Mst1<sup>−/−</sup> mice (Figure 5.6c).

5.2.2 Neutrophil adhesion under flow conditions

To verify the in vivo results described above, neutrophil adhesion was investigated under flow conditions ex vivo and under static conditions in vitro.

In ex vivo flow chamber assays, glass capillaries were coated with a combination of E-selectin, ICAM-1 and CXCL1. In flow chambers coated with E-selectin alone or E-selectin/ICAM-1, a small number of leukocytes became adherent, while coating with E-selectin/ICAM-1/CXCL1 induced integrin activation and increased the number of adherent cells FOV⁻¹. For all groups, neutrophil adhesion was similar between WT and Mst1⁻/⁻ mice (Figure 5.7).

![Bar graph showing neutrophil adhesion of WT and Mst1⁻/⁻ mice in an ex vivo flow chamber](image)

Figure 5.7 Neutrophil adhesion of WT and Mst1⁻/⁻ mice in an ex vivo flow chamber
Whole mouse blood from WT or Mst1⁻/⁻ mice was perfused through micro flow chambers coated with E-selectin (E), E/ICAM-1 or E/ICAM-1/CXCL1 and the number of adherent neutrophils per field of view (FOV) assessed (n = 3, mean ± SEM, n.s., 2way ANOVA, Sidak’s multiple comparisons test).
Results

Figure 5.8 LFA-1 clustering in neutrophils under flow conditions
Whole mouse blood from WT or Mst1−/− mice labeled with anti LFA-1 antibody (fluorescence intensity scale) was perfused through micro flow chambers coated with E-selectin, ICAM-1 and CXCL1. (n= 3 mice, one representative picture is shown).

To further elucidate, whether MST1 deficiency affected LFA-1 clustering of neutrophils during adhesion in flow chambers, LFA-1 localization was compared in WT and Mst1−/− neutrophils. Whole blood was collected and incubated with a non-blocking anti-LFA-1 antibody (clone 2D7) conjugated with Alexa Fluor® 546. Whole blood was perfused through E-selectin/ ICAM-1/ CXCL1 coated glass capillaries. Neutrophils adhering to the coated surfaces were recorded using confocal microscopy. Both, WT as well as Mst1−/− neutrophils displayed similar LFA-1 localization under flow, resulting in accumulation of LFA-1 at the uropod of neutrophils (Figure 5.8).

5.2.3 Surface expression and function
The surface expression of the alpha subunit of LFA-1 (CD11a, αL), the alpha subunit of Mac-1 (CD11b, αM), CXCR2, CD44, PSGL1 and L-selectin (CD62L) was investigated, to exclude any effects resulting from differences in the expression levels of those adhesion relevant molecules. Analyzing neutrophils, derived from blood and bone marrow, from WT and Mst1−/− mice no difference was found in expression levels of LFA-1, Mac-1, CXC2, CD44, PSGL-1 and CD62L (Figure 5.9).
Figure 5.9 Surface expression of adhesion relevant molecules on WT and *Mst1*<sup>−/−</sup> neutrophils
(a) Representative histograms showing expression of isotype control (grey), WT neutrophils (black) and *Mst1*<sup>−/−</sup> neutrophils (blue), respectively. (b) Mean fluorescence intensity (MFI) ratio (relative to isotype control) of CD11a, CD11b, CXCR2, CD44, PSGL1, CD62L on WT (black) and *Mst1*<sup>−/−</sup> neutrophils (grey) (n=3, mean ± SEM, p<0.01, unpaired t-test).

**E- and P-selectin binding to neutrophils**

To investigate the binding capacity of selectins to selectin ligands on neutrophils derived from WT and *Mst1*<sup>−/−</sup> mice, the binding of soluble selectin chimera was compared between WT and *Mst1*<sup>−/−</sup> neutrophils. E- or P-selectin hFc-chimeric proteins were incubated with whole blood from WT and *Mst1*<sup>−/−</sup> mice, with or without EDTA (negative control). The binding of E- or P-selectins were analyzed using flow cytometry. Both, neutrophils from WT and *Mst1*<sup>−/−</sup> mice, bound E-selectin and P-selectin to the same extent (Figure 5.10).
Soluble ICAM-1 binding to neutrophils

Next, the capacity of neutrophils to bind ICAM-1, which is dependent on the integrin activation status of LFA-1, was investigated. To do this, bone marrow derived neutrophils were isolated from WT and Mst1^-/- mice, unstimulated or stimulated with CXCL1. The capacity of WT or Mst1^-/- neutrophils to bind soluble ICAM-1 was analyzed using flow cytometry. No difference could be observed in CXCL1-dependent LFA-1 activation between WT and Mst1^-/- neutrophils (Figure 5.11a and Figure 5.11b).

Figure 5.10 E-selectin and P-selectin binding to WT and Mst1^-/- neutrophils
FACS analysis of (a) E-selectin IgG chimera binding or (b) P-selectin IgG chimera binding, performed with WT (black) or Mst1^-/- (grey) neutrophils (n=3, n.s., unpaired t-test).

Figure 5.11 CXCL1 dependent ICAM-1 binding to WT or Mst1^-/- neutrophils
FACS analysis of ICAM-1 binding, with or without CXCL1 stimulation, to (a) WT (black) or (b) Mst1^-/- (grey) neutrophils (n=5, * p < 0.05, ** p<0.01 paired t-test).
5.2.4 Neutrophil Adhesion in Patients with STK4 Deficiency

We had the rare opportunity to investigate the adhesive properties of neutrophils from two patients with STK4 deficiency and their heterozygote parents (Abdollahpour et al., 2012). These experiments were realized in cooperation with Dr. Claudia Nussbaum and Prof. Dr. Christoph Klein (LMU, München). Human neutrophils were isolated from whole blood. Glass capillaries coated with a combination of E-selectin/ ICAM-1/ IL-8, were then perfused with the isolated neutrophils. The number of adherent leukocytes FOV$^{-1}$ of STK4$^{-/-}$ patients and their heterozygous (STK4$^{+/-}$) parents increased to a similar extent with increased perfusion time (Figure 5.12).

Altogether, these in vitro and in vivo results demonstrate that, in contrast to T cells, MST1 is dispensable for LFA-1 activation and clustering in neutrophils. Hence, neutrophil adhesion is unaffected in Mst1$^{-/-}$ mice as well as in patients with STK4 deficiency.

Figure 5.12 MST1 is dispensable for neutrophil adhesion in humans
Number of adherent cells FOV$^{-1}$ from two patients with STK4 deficiency and their heterozygous parents was assessed over time in flow chambers coated with E-selectin/ ICAM-1/ CXCL8. (n=2 per group, chambers ≥ 2 per group, mean ± SEM)
5.3 MST1 IS CRITICAL FOR NEUTROPHIL EXTRAVASATION IN VIVO

Hence, the last step of the neutrophil adhesion cascade consisting in transmigration through the venular wall and extravasation into the interstitial space was investigated to elucidate the role of MST1 in this process.

5.3.1 TNF-α INDUCED NEUTROPHIL EXTRAVASATION INTO THE PERITONEAL CAVITY

The number of extravasated neutrophils in the TNF-α induced peritonitis model was evaluated. In WT mice, i.p. injection of 1µg TNF-α dramatically increased the number of neutrophils in the peritoneum as compared to NaCl control injection. In contrast, neutrophils from Mst1−/− mice failed to transmigrate into the peritoneal cavity 2 h after TNF-α stimulation (Figure 5.13).

Figure 5.13 TNF-α induced peritonitis in WT and Mst1−/− mice
Total number of extravasated neutrophils in the peritoneal lavage was quantified 2 h after i.p. injection of NaCl or 1µg TNF-α (n=3, mean ± SEM, * p < 0.05, 2way ANOVA, Sidak’s multiple comparisons test).
To accurately investigate the exact role of MST1 in neutrophil extravasation in vivo, multi-photon laser scanning microscopy of the mouse cremaster muscle was used. To do this, Lyz2\(^{GFP}\) mice (Faust et al., 2000), in which neutrophils are endogenously labeled with EGFP, were crossed with Mst1\(^{-/-}\) mice, to generate Mst1\(^{-/-}\) x Lyz2\(^{GFP}\) mice. As in WT and Mst1\(^{-/-}\) mice (Figure 5.2), the number of peripheral lymphocytes was decreased in Mst1\(^{-/-}\) x Lyz2\(^{GFP}\) mice compared with Lyz2\(^{GFP}\) mice. Neutrophil counts (Figure 5.14a) as well as the proportion of EGFP\(^{+}\) neutrophils and monocytes (Figure 5.14b) were similar between Lyz2\(^{GFP}\) and Mst1\(^{-/-}\) x Lyz2\(^{GFP}\) mice.

![Figure 5.14 Differential blood count from Lyz2\(^{GFP}\) and Mst1\(^{-/-}\) x Lyz2\(^{GFP}\) mice](image)

Differential blood counts of Lyz2\(^{GFP}\) (black, n= 5) and Mst1\(^{-/-}\) x Lyz2\(^{GFP}\) mice (grey, n= 4) (mean ± SEM, ***, p < 0.001, 2way ANOVA, Sidak’s multiple comparisons test). K = 1000

To visualize neutrophil extravasation, TNF-\(\alpha\) was injected into the scrotum of Lyz2\(^{GFP}\) and Mst1\(^{-/-}\) x Lyz2\(^{GFP}\) mice together with a non-blocking antibody against PECAM-1 (clone 390) conjugated with Alexa Fluor 546 to label endothelial cell junctions (Woodfin et al., 2011). Neutrophil crawling and transmigration was investigated between 180 and 240 min after TNF-\(\alpha\) injection.
Figure 5.15 Mst1<sup>−/−</sup> neutrophils fail to transmigrate into inflamed tissue
Neutrophils (green) and the microvasculature (PECAM-1, red) of TNF-α stimulated mouse cremaster muscle. (a) Neutrophil transmigration in Lyz2<sup>GFP</sup> and the accumulation of neutrophils in Lyz2<sup>GFP</sup> x Mst1<sup>−/−</sup> mice (with arrow) at 180 min, 210 min and 240 min after i.s. injection of TNF-α. Images were obtained using intravital multi photon microscopy (n= 3). (b) Intravascular crawling velocity of neutrophils in Lyz2<sup>GFP</sup> and Lyz2<sup>GFP</sup> x Mst1<sup>−/−</sup> mice (n= 3 mice, scatter blot with median of > 30 analyzed cells per group, *** p < 0.001, unpaired t test). (c) Transmigration time of Lyz2<sup>GFP</sup> and Lyz2<sup>GFP</sup> x Mst1<sup>−/−</sup> neutrophils. Cut off was set at 20 min (n= 3 mice, scatter blot with median of > 30 analyzed transmigration events per group, *** p < 0.001, Mann Whitney test).
During the time of observation, an increasing number of GFP+ neutrophils crossed the venule and migrated into the inflamed tissue in Lyz2GFP mice (Figure 5.15a, upper panel). In contrast, most neutrophils in Mst1−/− x Lyz2GFP mice remained closely associated with the abluminal side of the vessel (Figure 5.15a, lower panel, white arrow) and were unable to migrate further into the inflamed tissue. In addition, intravascular crawling velocity of neutrophils was reduced in Mst1−/− x Lyz2GFP mice compared to Lyz2GFP mice (Figure 5.15b). Furthermore, neutrophil transmigration of postcapillary venules in Lyz2GFP mice required 7.5 ± 0.8 min (median ± SEM), which was similar to the time reported by others (Woodfin et al., 2011). In contrast, most neutrophils in Mst1−/− x Lyz2GFP mice failed to transmigrate from the vessels within a 20 min observation period (20 ± 0.8 min, median ± SEM) (Figure 5.15c). Instead, Mst1−/− x Lyz2GFP neutrophils accumulated at the abluminal side of postcapillary venules where they remained for the whole time of observation (Figure 5.16, lower panel, white circle).
Interestingly, the total number of neutrophils within the cremaster muscle was similar between WT and Mst1<sup>−/−</sup> mice, 2 h after TNF-α injection (Figure 5.17a). Furthermore the viability (Figure 5.17b) and apoptosis rate of isolated neutrophils (Figure 5.17c) was similar between WT and Mst1<sup>−/−</sup> mice.

5.3.3 Laser Injury Induced Neutrophil Swarming

To test, whether further stimulation could induce migration into the interstitial space, a laser injury near postcapillary venules was induced 3 h after TNF-α stimulation. Neutrophils of Lyz2<sup>GFP</sup> mice swarmed and accumulated at the site of laser injury within 30 min, as described by Lämmermann et al. (Lammermann et al., 2013). Interestingly, neutrophils deficient in MST1 remained at the abluminal site of venules and were unable to migrate to the site of laser injury (Figure 5.18a), suggesting that they could not overcome the vessel wall. The green fluorescence intensity at the site of laser injury (white square) was measured over time, as a read out for the accumulation of EGFP<sup>+</sup> neutrophils. In Lyz2<sup>GFP</sup> mice a continues increase of green fluorescence intensity could be observed over time, which was completely absent in Mst1<sup>−/−</sup> x Lyz2<sup>GFP</sup> mice (Figure 5.18b).
Figure 5.18 Laser induced injury in the mouse cremaster muscle

(a) Representative images of swarming neutrophils (green) and the microvasculature (PECAM-1, red) in the mouse cremaster muscle of Lyz2\textsuperscript{GFP} and Lyz2\textsuperscript{GFP} x Mst1\textsuperscript{-/-} mice after induction of a laser injury (white square). (b) Intensity profile of the GFP signal in Lyz2\textsuperscript{GFP} and Lyz2\textsuperscript{GFP} x Mst1\textsuperscript{-/-} mice at the site of laser injury (n=3, mean ± SEM, p< 0.05 after 12 min, ** p < 0.01, 2way ANOVA, Sidak’s multiple comparisons test).
To exclude migration defects within the interstitial matrix, a process which can occur in an integrin independent fashion (Wolf et al., 2009, Lammermann et al., 2008), migration in 3D collagen gels (integrin independent migration assay) was compared between WT and Mst1−/− neutrophils in cooperation with Babara Walzog. The absence of MST1 did not affect migration in 3D collagen gels (see Appendix/Manuscript/Supplemental Figure 2).

Furthermore, the phagocytic capacity within the first 15 min of WT and Mst1−/− neutrophils was similar (Figure 5.19), although others showed impaired phagocytosis of conditional Mst1−/− Mst2−/− double knockout neutrophils after 50 min of injection (Geng et al., 2015).

Taken together, these results suggest that neutrophils from Mst1−/− mice fail to completely extravasate from postcapillary venules, but are functionally capable of migrating in the interstitial matrix and phagocytosing pathogens.

Figure 5.19 Phagocytic capacity of WT and Mst1−/− neutrophils
Flow cytometry of WT and Mst1−/− neutrophils infected with pHrodoTM E.coli BioParticles for 15 min at 4°C (no phagocytosis) and 37°C (n=3 mice, mean ± SEM, n.s., 2way ANOVA, Sidak’s multiple comparisons test).
5.3.4 Neutrophil Penetration Through the Venular Basement Membrane

To better define at which step during transmigration neutrophils from Mst1−/− mice were inhibited, we cooperated with Dietmar Vestweber to investigate the capacity of neutrophils to migrate through the endothelium and penetrate the perivascular basement membrane (BM) in more detail. Using confocal microscopy of TNF-α stimulated cremaster muscles whole mount, we discovered that neutrophils of Mst1−/− mice accumulated between the endothelium and the BM, compared to WT mice (Bixel et al., 2010) (see Appendix/Manuscript/ Figure 4A-C).

To verify these results in vitro, transmigration assays using CXCL1 as a chemoattractant were performed. First, transwell filters were coated with BSA (control), laminin, a key component of the BM (Yousif et al., 2013), or laminin combination with PECAM-1 and ICAM-1. Laminin alone did not allow transmigration of unstimulated WT or Mst1−/− neutrophils. The number of transmigrated WT or Mst1−/− neutrophils through laminin-coated filters in response to CXCL1 increased and was comparable to transmigration through BSA-coated filters in the absence of a chemoattractant.

However, additional coating with PECAM-1 and ICAM-1 of laminin coated filters efficiently induced neutrophil transmigration along a CXCL1 gradient in WT neutrophils (Figure 5.20a). These findings are in line with previously published data (Wang et al., 2005). Conversely the number of transmigrated Mst1−/− neutrophils did not increase when laminin coated filters were additionally coated with PECAM-1 and ICAM-1 (Figure 5.20a).

In line with this finding, Mst1−/− neutrophils failed to transmigrate as efficiently as WT neutrophils in response to CXCL1 through filters containing a monolayer of mouse endothelial 1G11 cells, which forms its own extracellular matrix (Figure 5.20b). Importantly, we did not find differences in transmigrated WT and Mst1−/− neutrophils in transwell assays without coating (Figure 5.20c).
Figure 5.20 *Mst1*−/− neutrophils show reduced penetration of laminin or endothelial cell coated, but not uncoated transwells
Transmigration of neutrophils in transwell assays (a) with or without CXCL1 stimulation through BSA (control), laminin-1 (LN-1) and LN-1, PECAM-1 and ICAM-1 coated filters (n= 3 mice, mean ± SEM, *** p < 0.001, ** p < 0.01, 2way ANOVA, Sidak’s multiple comparisons test), (b) with or without CXCL1 stimulation through an endothelial monolayer of 1G11 cells (n= 3 mice, mean ± SEM, *** p < 0.001, 2way ANOVA, Sidak’s multiple comparisons test), (c) to HBSS, 10ng ml⁻¹ and 100ng ml⁻¹ CXCL1 (n= 3 mice, mean ± SEM., 2way ANOVA, Sidak’s multiple comparisons test).

These results demonstrate that MST1 is essential for neutrophils to penetrate the BM *in vivo* and *in vitro.*
5.4 MST1 REGULATES VESICLE TRAFFICKING IN NEUTROPHILS

5.4.1 MST1 INDUCED TRANSLOCATION OF VLA-3, VLA-6 AND NE TO THE CELL SURFACE

It was shown previously, that the mobilization of VLA-3 (CD49c, α3β1 integrin), VLA-6 (CD49f, α6β1 integrin) and NE (neutrophil elastase) from intracellular stores to the plasma membrane is a crucial step for successful neutrophil transmigration (Hyun et al., 2012, Lerman et al., 2014, Wang et al., 2005). In addition, it was reported that MST1 regulates vesicle trafficking in T cells (Nishikimi et al., 2014). In order to evaluate the putative role of MST1 in the mobilization of VLA-3, VLA-6 and NE, neutrophils from WT or Mst1⁻/⁻ mice were seeded on slides coated with BSA or PECAM-1/ ICAM-1/ CXCL1. After 30 min, cells were fixed, permeabilized and immunostained with antibodies against VLA-3, VLA-6 or NE. By means of confocal microscopy WT as well as Mst1⁻/⁻ neutrophils seeded on BSA displayed all three molecules - VLA-3, VLA-6 and NE (Figure 5.21a, c, e) - within intracellular stores. PECAM-1/ ICAM-1/ CXCL1 coating induced the translocation of VLA-3, VLA-6 and NE to the surface of interacting WT neutrophils, leading to a ring-like expression at the cell border (Figure 5.21a, c, e). Ring formation of VLA-3, VLA-6 and NE could be observed in 94.3 ± 4.3%, 80.9 ± 9.8% and 93.8 ± 3.6% of all analyzed WT neutrophils, respectively (Figure 5.21b, d, f). In contrast, neutrophils derived from Mst1⁻/⁻ mice failed to efficiently mobilize any of these three proteins to the cell surface (Figure 5.21a-i). Only 46.7 ± 7.6% of all analyzed Mst1⁻/⁻ neutrophils showed a ring formation for VLA-3, 17.4 ± 2.4% for VLA-6 and 22.5 ± 4.0% for NE. These values were similar to the values found for WT (31.6 ± 9.4% for VLA-3, 20.1 ± 8.9% for VLA-6, 23.4 ± 3.7% for NE) and Mst1⁻/⁻ (31.2 ± 6.6% for VLA-3, 4.8 ± 0.6% for VLA-6, 24.7 ± 4.4% for NE) neutrophils seeded on BSA (Figure 5.21b, d, f).
Results

Figure 5.21 MST1 is required for the translocation of NE, VLA-3 and VLA-6 to the plasma membrane
Immunostaining of representative WT and Mst1^-/- neutrophil on BSA or PECAM-1/ICAM-1/CXCL1 coated slides for (a) VLA-3, (c) VLA-6 and (e) NE. Quantification of ring like expression of (b) VLA-3, (d) VLA-6 and (f) NE (n= 3 mice, mean ± SEM of >50 analyzed neutrophils, *** p < 0.001, ** p < 0.01, 2way ANOVA, Sidak’s multiple comparisons test or Tukey’s multiple comparisons test).

Ring formation was further evaluated by measuring the fluorescence intensity profiles along a line through the center of the cell (Figure 5.22a). Fluorescence intensity profile of VLA-3, VLA-6 and NE were similar between WT or Mst1^-/- cells seeded on BSA (Figure 5.22b, c, d). Translocation of VLA-3, VLA-6 and NE to the plasma membrane of WT neutrophils increased the fluorescence signal at the cell boarders (Figure 5.22e, f, g, black line). In contrast, the accumulation of the fluorescence signal at the cell surface was absent for VLA-3, VLA-6 and NE in Mst1^-/- neutrophils (Figure 5.22e, f, g, grey line).
Figure 5.22 Fluorescence intensity profile of VLA-3, VLA6 and NE in neutrophils from WT and Mst1⁻/⁻ mice
(a) Fluorescence intensity profiles along a line through the cell center (red thick line) for (b) VLA-3, (c) VLA-6 and (d) NE seeded on BSA and for (e) VLA-3, (f) VLA-6 and (g) NE seeded on PECAM-1/ICAM-1/CXCL1 of a representative WT (black line) and Mst1⁻/⁻ neutrophil (grey line).

To unravel the ligand responsible for the translocation of VLA-3, VLA-6 and NE, WT neutrophils were either seeded on BSA, PECAM-1, ICAM-1/ CXCL1, or PECAM-1/ICAM-1/ CXCL1. WT neutrophils seeded on PECAM-1 coated coverslips alone induced the translocation of VLA-6 (63.0 ± 2.4%), but not NE (10.0 ± 5.0%). Whereas WT neutrophils seeded on ICAM-1/ CXCL1 coated coverslips translocated NE (63.1 ± 10.7%), but not VLA-6 (39.2 ± 7.5%) (Figure 5.23a and b). The results for VLA-3 were not conclusive.
Figure 5.23 Ligands responsible for VLA-6 and NE translocation
Quantification of ring like expression of (a) VLA-6 and (b) NE in WT neutrophil on BSA, PECAM-1, ICAM-1/CXCL1 or PECAM-1/ICAM-1/CXCL1 coating (n=3 mice, mean ± SEM of >50 analyzed neutrophils, *** p < 0.001, ** p < 0.01, one way ANOVA, Tukey’s multiple comparisons test).

Importantly, western blot analysis showed no difference in the total protein levels of VLA-3, VLA-6 and NE between WT and Mst1^{-/-} neutrophils (Figure 5.24).

Figure 5.24 Total Protein levels of VLA-3, VLA-6 and NE
Total protein levels of VLA-3, VLA-6 and NE from neutrophils of WT and Mst1^{-/-} mice. GAPDH served as loading control (n=3 mice).
In order to verify MST1 dependent mobilization in vivo, NE activity was investigated with an NE-fluorescent activatable substrate (NE680FAST) in postcapillary venules of unstimulated and TNF-α stimulated cremaster muscle whole mounts from WT and Mst1^−/− mice.

**Figure 5.25 NE activity in TNF-α stimulated cremaster muscle in vivo**
Confocal images of unstimulated and TNF-α stimulated cremaster muscle whole mounts from WT and Mst1^−/− mice showing NE activity (white) within venules labels with PECAM-1 (red). (n=3)
In unstimulated venules of WT mice NE activity could not be detected, while 2h after TNF-α stimulation NE activity could be observed (Figure 5.25a). TNF-α stimulated venules from Mst1−/− mice showed decreased NE activity as compared to WT mice (Figure 5.25a). Importantly, the number of adherent cells was similar in WT and Mst1−/− mice (Figure 5.25b). Furthermore occasionally high NE activity close to the vessel could be observed. Using 3D reconstruction, a ring like NE activity close to the abluminal site of the vessel could be detected, although only very few events were noted (Figure 5.25c).

Taken together, these *in vitro* and *in vivo* results demonstrate that MST1 is indispensable for efficient translocation of VLA-3, VLA-6 and NE to the surface of neutrophils.

### 5.4.2 MST1 AND RAB27A IN VESICLE TRAFFICKING

Rab27a is a central regulator of vesicle trafficking in neutrophils (Catz, 2014, Sheshachalam et al., 2014). Therefore, Rab27a translocation to the plasma membrane in response to PECAM-1/ ICAM-1/ CXCL1-stimulation was investigated. Rab27a displayed an intracellular localization in WT and Mst1−/− neutrophils when seeded on BSA (Figure 5.26a and b). Rab27a showed a granular distribution in WT neutrophils, while the distribution was more homogenous in Mst1−/− neutrophils. Furthermore, in WT neutrophils, PECAM-1/ ICAM-1/ CXCL1-coating induced the translocation of Rab27a to the plasma membrane (Figure 5.26a, upper, right panel). Again, the translocation of Rab27a to the plasma membrane of WT neutrophils transferred the main fluorescence to the cell border (Figure 5.26c, black line). Ring formation of Rab27a was observed in 78.0 ± 6.5% of all analyzed WT neutrophils, compared to 11.7 ± 3.7% of WT neutrophils seeded on BSA (Figure 5.26d). In contrast, neutrophils derived from Mst1−/− mice displayed a reduced translocation rate of Rab27a to the plasma membrane in response to PECAM-1/ ICAM-1/ CXCL1 stimulation (Figure 5.26a, lower panel). Only 1.7 ± 1.7% of all analyzed Mst1−/− neutrophils showed a ring formation for Rab27a and 17.7 ± 7.5% of Mst1−/− neutrophils seeded on BSA (Figure 5.26d). Hence, Mst1−/− neutrophils display a defect in Rab27a mobilization upon stimulation with ICAM-1/ PECAM-1/ CXCL1.
Figure 5.26 Rab27a translocation to the plasma membrane in Mst1\(^{-/-}\) neutrophils
(a) Immunostaining of WT and Mst1\(^{-/-}\) neutrophils seeded on BSA or PECAM-1/ICAM-1/CXCL1 coated wells for Rab27a. (b, c) Fluorescence intensity profiles along a line through the cell center for Rab27a of representative WT (black line) and Mst1\(^{-/-}\) neutrophil (grey line) seeded on (b) BSA or (c) PECAM-1/ICAM-1/CXCL1 coated wells. (d) Quantification of ring like expression of Rab27a (n= 3 mice, mean ± SEM of >50 analyzed neutrophils, *** p < 0.001, unpaired t-test).

Interestingly, total protein levels of Rap27 were similar between WT and Mst1\(^{-/-}\) neutrophils (Figure 5.27).

Next, the translocation of MST1 itself to the plasma membrane upon PECAM-1/ICAM-1/CXCL1 stimulation was investigated. MST1 displayed an intracellular localization in WT neutrophils seeded on BSA (Figure 5.28a, upper panel and Figure 5.28b, grey line). In response to PECAM-1/ICAM-1/CXCL1 stimulation, MST1 localized together with Rab27a and VLA-6 to the plasma membrane (Figure 5.28a, lower panel and Figure 5.28b, black line). Only 11.8 ± 7.2% of analyzed WT neutrophils seeded on BSA showed a ring formation for MST1, seeding neutrophils on PECAM-1/ICAM-1/CXCL1 resulted in a ring formation of MST1 in 93.2 ± 1.6% of analyzed WT neutrophils (Figure 5.28c).

Figure 5.27 Total protein levels of Rab27a
Total protein levels of Rab27a from neutrophils of WT and Mst1\(^{-/-}\) mice. GAPDH served as loading control (n=3 mice).
These results demonstrate that Rab27a and MST1 translocate to the cellular membrane upon ICAM-1/ PECAM-1/ CXCL1 stimulation. Hence, we hypothesize, that MST-1 is involved in Rab27a dependent vesicle transport.
6 DISCUSSION

Originally, MST1 (mammalian homolog of the *Drosophila* Hippo protein) was identified in *Drosophila* as the central constituent and negative regulator of the Hippo pathway, controlling organ size and proliferation. Recently, MST1 has attracted more attention due to its role in cancer development (Kodaka and Hata, 2015) and the discovery that mutations in human *STK4* (Mst1) lead to a primary immune deficiency. Patients with a deficiency in *STK4* present with recurring bacterial, fungal and viral infections, they display lymphopenia and intermittent neutropenia, and their life expectancy is very short unless successfully transplanted (Abdollahpour et al., 2012, Crequer et al., 2012, Nehme et al., 2012, Dang et al., 2016, Halacli et al., 2015). Together with neutropenia, their impaired response to acute bacterial and fungal infections suggests an additional defect in myeloid cell function.

Until now, little is known about the function of MST1 in myeloid cells. One study suggested a role for MST1 in human eosinophil apoptosis, but not neutrophil apoptosis (De Souza et al., 2002). In contrast, neutrophils from patients with *STK4* deficiency exhibit an increased susceptibility to apoptosis (Abdollahpour et al., 2012). A recent study linked MST1 and MST2 in phagocytes (macrophages and neutrophils) to the recruitment of mitochondria to the phagosome. The fusion of mitochondria with the phagosome leads to increased ROS production and consequently promotes effective killing of bacteria (Geng et al., 2015). The aim of this thesis was to investigate how MST1 deficiency affects neutrophil recruitment *in vivo*.

The experimental work presented here, discovered that MST1 deficiency does not affect neutrophil rolling and adhesion, but extravasation of neutrophils. In contrast to T cells (Katagiri et al., 2006, Katagiri et al., 2009), MST1 is dispensable for activation of LFA-1 in neutrophils, identified as the first signaling molecule indispensable for neutrophil transmigration, in particular the penetration of neutrophils through the perivascular basement membrane. Mechanistically, *Mst1*−/− neutrophils fail to translocate VLA-3, VLA-6 and neutrophil elastase form intracellular vesicles to the neutrophil surface, a putative requirement for neutrophils to successfully penetrate the basement membrane.
6.1 CHARACTERIZING MST1 IN NEUTROPHILS

First, the expression of MST1 and MST2 in murine neutrophils was evaluated, due to conflicting results in the past. De Souza and colleges investigated the expression of MST1 and MST2 in neutrophils and eosinophils and could only detect expression of MST1 and MST2 in eosinophils, but not in neutrophils (De Souza et al., 2002). In contrast, here it is demonstrated that murine neutrophils from WT mice express MST1, but not MST2. In addition, the absence of MST1 in neutrophils from Mst1−/− mice could be confirmed. As MST1 is rapidly cleaved in neutrophil lysates into the 37kDa N-terminal fragment, which cannot be detected by all of the available antibodies, the absence of MST1 in De Souza’s work may be explained by the use of antibodies unable to recognize the fragment. Here, the expression of MST1 was verified with antibodies against MST1 from two different companies. One antibody is specific for the C-terminal fragments for MST1 (Upstate; 276-487aa) and the other antibody recognizes the N-terminal region of MST1 (Cell Signaling). In accordance with data published by De Souza et al., we also could not detect the expression of MST2 in neutrophils, neither in WT nor Mst1−/− neutrophils. Next, peripheral blood counts in WT and Mst1−/− mice were compared. As reported by others (Oh et al., 2009, Mou et al., 2012), white blood cell counts were significantly decreased due to a decreased number of peripheral lymphocytes. This was also discovered in patients with STK4 deficiency (Abdollahpour et al., 2012, Crequer et al., 2012, Nehme et al., 2012, Dang et al., 2016, Halacli et al., 2015). However, in contrast to human patients (Abdollahpour et al., 2012), the number of peripheral neutrophils was similar between WT and Mst1−/− mice. In addition, the absence of MST1 in murine neutrophils did not increase susceptibility to apoptosis in contrast to neutrophils from patients with STK4 deficiency (Abdollahpour et al., 2012). Differences in neutrophil counts between the human and the murine system could also be observed for other genes causing congenital neutropenia (CN) or severe congenital neutropenia (SCN) (Klein, 2011). The two most common genetic etiologies of SCN, HAX1 and ELA2 deficiency lead to SCN only in humans, but Hax1−/− and Ela2−/− mice do not display neutropenia (Belaaouaj et al., 1998, Chao et al., 2008, Dale et al., 2000, Horwitz et al., 1999, Horwitz et al., 2007, Klein et al., 2007), indicating a different regulation of neutrophil apoptosis between humans and mice.
6.2 MST1 IS DISPENSABLE FOR LFA-1 ACTIVATION IN NEUTROPHILS

The canonical Hippo (MST1/2) pathway is known for controlling proliferation and apoptosis, tissue growth, organ size and tumorigenesis. However, there is emerging evidence that various non-canonical Hippo pathways regulate other biological processes, often in a cell type specific manner. Recent studies have revealed that MST1 is involved in T cell development, function, survival, trafficking, homing and autoimmunity (Du et al., 2015).

MST1 was shown to be required for LFA-1 dependent T cell trafficking (Dong et al., 2009, Ueda et al., 2012, Katagiri et al., 2009), by regulating the transport and distribution of LFA-1 containing vesicles to the plasma membrane and by subsequently influencing LFA-1 activation, clustering and adhesion of T cells (Katagiri et al., 2006). Furthermore, Nishikimi et al. showed that MST1 associates via Rap1-RAPL to the cytoplasmic tail of the αL subunit (Katagiri et al., 2006, Katagiri et al., 2003). This in turn is followed by phosphorylation of DENND1C, a Rab guanyl-nucleotide exchange factor, which results in Rab13-dependent LFA-1-containing vesicle transport (Nishikimi et al., 2014).

In contrast to T cells (Katagiri et al., 2006, Katagiri et al., 2009), it could be demonstrated that Mst1−/− neutrophils have no defect in LFA-1-dependent slow rolling and adhesion implying that MST1 is dispensable for LFA-1 activation in neutrophils. The absence of MST1 did not influence the number of rolling neutrophils or rolling velocities in postcapillary venules of trauma stimulated or TNF-α stimulated cremaster muscles in vivo. Under inflammatory conditions, E-selectin and P-selectin induce talin dependent conformational changes in LFA-1 which leads to intermediate activity and slow rolling of neutrophils in post postcapillary venules (McEver, 2015). Both, neutrophils from WT and Mst1−/− mice, bound E-selectin and P-selectin to the same extent and no difference in the surface expression of rolling and adhesion relevant molecules could be observed between WT and Mst1−/− neutrophils.

Additional activation, for example by chemokine stimulation, results in the binding of both, kindlin3 and talin1, to the cytoplasmic tail of the β subunit of LFA-1, leading to the high affinity conformation of LFA1 (Lefort et al., 2012). High affinity conformation of
LFA-1 increases the affinity to endothelial expressed ICAM1 and ICAM2 leading to firm arrest of neutrophils (Lefort and Ley, 2012). Consistent with the hypothesis that MST1 does not regulate LFA-1 activity in neutrophils, no difference in adhesive properties of neutrophils in postcapillary venules of trauma and TNF-α stimulated cremaster muscle of WT and Mst1−/− mice was observed. Also LFA-1 dependent neutrophil adhesion induced by i.v. injection of CXCL1 in vivo, activating LFA-1 via integrin inside-out signaling, showed no difference between WT and Mst1−/− mice.

To exclude compensatory effects from the endothelium, ex vivo flow chambers coated with a combination of E-selectin, ICAM-1 and CXCL1 were used to confirm in vivo findings. Neutrophils from WT and Mst1−/− mice adhered to a similar extent to E-selectin, E-selectin/ ICAM-1 and E-selectin/ ICAM-1/ CXCL1 coated flow chambers.

In addition, LFA-1 clustering under flow conditions, as well as LFA-1 activation, measured using a soluble ICAM-1 binding assay, and the surface expression of LFA-1 and Mac-1 was not altered in Mst1−/− neutrophils compared to WT neutrophils.

Finally, we were able to investigate the adhesive properties of neutrophils from patients with STK4 deficiency and their heterozygous parents with the help from Dr. Claudia Nussbaum and Prof. Dr. Christoph Klein (Dr. von Hauner Children’s hospital, LMU, Munich). Using flow chambers coated with E-selectin/ ICAM-1/ CXCL8, we could demonstrate that MST1 was also dispensable for neutrophil adhesion in the human system.

These results suggest that different mechanisms of LFA-1 regulation/ activation exist between lymphocytes and neutrophils. This hypothesis is supported by data from Fabbri et al., reporting that Rab11, but not Rab13 (as in T cells), is required for the trafficking of LFA-1 containing vesicles in neutrophils (Fabbri et al., 2005).
6.3 MST1 IS CRITICAL FOR NEUTROPHIL EXTRAVASATION

Although $Mst1^{-/-}$ neutrophils showed no defective rolling or adhesion, they failed to extravasate into the peritoneal cavity 2h after TNF-α stimulation.

To accurately investigate the exact role of MST1 in neutrophil extravasation *in vivo*, an imaging platform using multi-photon laser scanning microscopy in the mouse cremaster muscle was established. To this end, $Mst1^{-/-}$ mice were crossed with $Lyz2^{GFP}$ mice, in which neutrophils are endogenously labeled with EGFP. $Mst1^{-/-} \times Lyz2^{GFP}$ mice displayed a decreased number of peripheral lymphocytes compared to $Lyz2^{GFP}$ mice. Importantly, the numbers of neutrophils as well as the proportion of EGFP$^+$ neutrophils and monocytes were similar between $Lyz2^{GFP}$ and $Mst1^{-/-} \times Lyz2^{GFP}$ mice. Neutrophil transmigration was then observed in postcapillary venules of TNF-α stimulated cremaster muscles with endothelial cells stained with Alexa Fluor 546 conjugated anti-PECAM-1 antibody (Christofidou-Solomidou et al., 1997, Woodfin et al., 2011). $Mst1^{-/-}$ neutrophils failed to properly extravasate from postcapillary venules to the site of inflammation. Instead, neutrophils remained in close contact with the abluminal side of the vessel. Interestingly, the total number of neutrophils within the cremaster muscle was similar between WT and $Mst1^{-/-}$ mice. Even after additional stimulation by inducing a laser injury next to the vessel 4 h after TNF-α stimulation, $Mst1^{-/-}$ neutrophils persisted at the vessel wall and failed to migrate to the site of injury. Effects due to decreased viability could be excluded as neutrophils isolated from the TNF-α stimulated cremaster muscle showed no difference in viability.

Interstitial matrix migration can be integrin independent (Wolf et al., 2009, Lammermann et al., 2008). In order to exclude a general migration defect of $Mst1^{-/-}$ neutrophils, migration of WT and $Mst1^{-/-}$ neutrophils was investigated in 3D collagen gels by the group of Prof. Barbara Walzog, Walter-Brendel-Center of Experimental Medicine, LMU, Munich. They tested migration of bone marrow-derived neutrophils within 3D collagen gels in response to fMLP or CXCL1. The absence of MST1 did not alter the 3D migration capacity of neutrophils (see Appendix/Manuscript/Supplemental Figure 2), indicating that MST1 does not affect migration in 3D collagen gels.
Additionally, the imaging approach using multi-photon laser scanning microscopy of the mouse cremaster muscle allowed us to investigate neutrophil crawling on the luminal side of postcapillary venules \textit{in vivo}. $\text{Mst}1^{-/-} \times \text{Lyz}2^{GFP}$ neutrophils showed a decreased crawling velocity compared to $\text{Lyz}2^{GFP}$ neutrophils, suggesting that MST1 regulates neutrophil crawling \textit{in vivo}.

### 6.3.1 Neutrophil Transmigration in a \textit{H. pylori} Mouse Infection Model

In order to evaluate the impact of MST1 deficiency in neutrophils during a clinically relevant infection, the group of Prof. Rainer Haas, Max von Pettenkofer-Institute, LMU, Munich evaluated the role of MST1 in a murine \textit{Helicobacter pylori} (\textit{H. pylori}) infection model. More than 50\% of the human population suffers from chronic \textit{H. pylori} infection, which makes this gram-negative bacterium one of the most successful human bacterial pathogens. While most infected people are asymptomatic, about 15-20\% develop chronic gastritis, duodenal ulcers, or even adenocarcinoma or mucosa-associated lymphoid tissue (MALT) lymphoma. Previous work has shown that neutrophils play an important role in the pathogenesis of \textit{H. pylori} (Kusters et al., 2006). The bacterium induces a strong inflammatory response in the gastric mucosa, which is dependent on \textit{H. pylori} neutrophil-activating protein (HP-NAP). Furthermore, pro-inflammatory cytokines like CXCL8 (IL-8) are secreted during the inflammatory process, recruiting additional neutrophils and monocytes to the site of inflammation (Montecucco and Rappuoli, 2001).

WT and $\text{Mst}1^{-/-}$ mice were orogastrically infected with \textit{H. pylori} and sacrificed 3 months later, when a chronic gastric infection was established. Tissue sections of the gastric epithelium from the antrum and corpus of the stomach were immunostained with DAPI and anti-mouse Ly6G antibodies, to identify neutrophils. The antrum is known to be the major site of \textit{H. pylori} infection (Sachs et al., 2003). Indeed, the majority of infiltrated neutrophils were found in the antrum and not in the corpus in WT mice (\textit{see Appendix/ Manuscript/ Figure 3A}, upper panel). In contrast, only a very small number of neutrophils could be detected in the gastric epithelium of the antrum in $\text{Mst}1^{-/-}$ mice (\textit{see Appendix/ Manuscript/ Figure 3A}, lower panel). The number of extravasated neutrophils in the antrum was significantly reduced in $\text{Mst}1^{-/-}$ mice compared to WT mice (\textit{see Appendix/ Manuscript/ Figure 3B}). In line with the reduced number of
extravasated neutrophils in $Mst1^{-/-}$ mice, the number of the colony forming units (cfu) of $H. pylori$ in the antrum showed a significant increase in $Mst1^{-/-}$ mice compared to WT mice (see Appendix/Manuscript/Figure 3C), indicating a more successful colonization.

To distinguish if the increased colonization in the antrum of $Mst1^{-/-}$ mice results from defects in transmigration and/or defects in the phagocytosis, the phagocytic capacity of $Mst1^{-/-}$ neutrophils was evaluated. The phagocytic capacity of neutrophils was not impaired within the first 15 min in absence of MST1. This is line with another study (Geng et al., 2015). However, they reported impaired phagocytosis of conditional $Mst1^{-/-}Mst2^{-/-}$ double knockout neutrophils after 50 min (Geng et al., 2015). Within this study later time points were not investigated, therefore it cannot be excluded that $Mst1^{-/-}$ single knockout neutrophils display defects after 50 min.

These results suggest that the increase in colonization in $Mst1^{-/-}$ mice is due to the inability of neutrophils to migrate to the site of inflammation, although an additional role of MST1 in phagocytosing the pathogens cannot be completely exclude.

6.3.2 NEUTROPHIL PENETRATION THROUGH THE VENULAR BASEMENT MEMBRANE

To better define at which step during transmigration neutrophils from $Mst1^{-/-}$ mice were inhibited (Figure 6.1), Prof.Dr. Dietmar Vestweber, Max-Planck-Institute for Molecular Biomedicine, Münster and his groups investigated in collaboration with our group the capacity of neutrophils to migrate through the endothelium and penetrate the perivascular basement membrane (BM) in more detail. To do this, whole mount immune stainings of TNF-α stimulated cremaster muscles were performed using antibodies against laminin α5 (LNα5) and the endothelial cell-specific adhesion molecule 1 (ESAM1) to visualize the BM and endothelial cell contacts, respectively. An antibody against MRP14 was used to identify neutrophils (see Appendix/Manuscript/Figure 4A). By means of confocal microscopy, neutrophils were classified into three groups according to their position during the extravasation from postcapillary venules. Neutrophils, embedded within the endothelial layer belonged to position I. Position II represents neutrophils located between the endothelium and BM
and fully transmigrated neutrophils were classified as position III (Bixel et al., 2010) (see Appendix/Manuscript/Figure 4B). 49.0 ± 3.9% of WT neutrophils were in intimate contact with the endothelium (position I), 16.4 ± 2.3% were found between the endothelium and the BM (position II) and 34.6 ± 3.8% were fully transmigrated (position III) 2h after TNF-α stimulation. Neutrophils of Mst1−/− mice were present at similar percentages embedded within the endothelium (position I, 43.0 ± 2.8%). However, almost the same amount of cells was located between the endothelium and the BM (position II, 41.8 ± 2.0%). Only 15.1 ± 2.2% of the Mst1−/− neutrophils were fully transmigrated (position III) (see Appendix/Manuscript/Figure 4C).

These data indicate that MST1 is crucial for neutrophils to overcome the basement membrane. This could not only be demonstrated in postcapillary venules of TNF-α stimulated cremaster muscles, but also in the submucosal vasculature and tissue of the H. pylori infected murine stomach of WT and Mst1−/− mice (see Appendix/Manuscript/Figure 3D-F).

Figure 6.1 Updated neutrophil adhesion cascade
Depicted are the sequential steps of neutrophil recruitment from the vasculature to the tissue.
6.3.3 MST1 AND TRANSLOCATION OF VLA-3, VLA-6 AND NE TO THE CELL SURFACE

After crossing the endothelial cell layer, neutrophils have to penetrate the underlying BM (Proebstl et al., 2012, Wang et al., 2006). The BM of postcapillary venules is mainly composed of laminin 411 (α4β1γ1 laminin subunit), laminin 511 (α5β1γ1 laminin subunit) and type IV collagen (Sorokin, 2010). Although many studies have been performed on leukocyte adhesion and TEM, the mechanisms by which neutrophils penetrate the BM are still poorly understood.

Previous studies showed that genetic, antibody or inhibitor-mediated blockade of PECAM-1 (Wang et al., 2005), VLA-3 (Hyun et al., 2012), VLA-6 (Dangerfield et al., 2002, Dangerfield et al., 2005, Wang et al., 2005) or NE (Wang et al., 2005) in the mouse cremaster muscle leads to an arrest of infiltrating neutrophils between the endothelial layer and the underlying BM. Extravasating neutrophils need to interact with ICAM-1 and PECAM-1 to induce the mobilization of vesicles containing VLA-6 and NE. This mobilization translocates VLA-6 and NE to the cellular surface, a prerequisite to pass the BM.

To prove this hypothesis, an in vitro transmigration assay was established where filters were coated with laminin, mimicking the basement membrane. Interestingly, WT as well as Mst1−/− neutrophils were unable to pass filters coated only with laminin. However, additional coating with PECAM-1 and ICAM-1 of laminin coated filters efficiently induced neutrophil transmigration along a CXCL1 gradient in WT neutrophils. These findings are in line with previously published data (Wang et al., 2005). Furthermore, in contrast to WT neutrophils, neutrophils from Mst1−/− mice failed to pass through PECAM-1, ICAM-1 and laminin-coated transwell filters. Similar to this finding, Mst1−/− neutrophils failed to transmigrate as efficiently as WT neutrophils through filters containing a monolayer of mouse endothelial 1G11 cells in response to CXCL1. Importantly, we did not find differences in the number of transmigrated WT and Mst1−/− neutrophils in transwell assays without coating.

Next, the mobilization of VLA-3, VLA-6 and NE from intracellular stores to the plasma membrane in the absence of MST1 was investigated. It was discovered that MST1 is essential for the exocytosis of VLA-3, VLA-6 and NE as neutrophils from Mst1−/− mice fail to translocate these proteins to the cell surface upon stimulation with PECAM-1, ICAM-1 and CXCL1. Further, it was demonstrated that ICAM-1 and CXCL1 coating are
responsible for the translocation of NE, whereas PECAM-1 lead to the mobilization of VLA-6. The results for VLA-3 were not conclusive.

Taken together, neutrophils deficient in MST1 fail to efficiently penetrate the basement membrane. This is accompanied by their inability to mobilize VLA-3, VLA-6 and/or NE from intracellular vesicles in response to interactions with endothelial CXCL-1, ICAM-1 and PECAM-1 (Figure 6.2).

6.3.4 MST1 TRANSLOCATION WITH Rab27a TO THE PLASMA MEMBRANE

As MST1 influences LFA-1 clustering in T cells by regulating LFA-1 containing vesicle trafficking via Rab13 (Nishikimi et al., 2014), we hypothesized, that MST1 is similarly involved in the mobilization of the vesicles containing VLA-3, VLA-6 and NE to the plasma membrane in neutrophils. The GTPase Rab27a is a central regulator of vesicle exocytosis, thus regulating a variety of neutrophil functions (Catz, 2014). Several studies indicate that Rab27a and its effectors JFC1 (synaptotagmin-like protein 1) and Munc13-4 regulate the secretion of several granules and vesicles, for example azurophilic granules containing e.g. NE (Brzezinska et al., 2008, Munafo et al., 2007). Rab27a and MST1 itself were discovered to translocate to the plasma membrane in response to PECAM-1/ICAM-1/CXCL1. However, translocation of Rab27a is defective in Mst1−/− neutrophils indicating that MST1 is involved in Rab27a dependent vesicle trafficking. Further studies may elucidate, whether Rab27a regulates only NE secretion or is additionally involved in VLA-3 and VLA-6 translocation.
Figure 6.2 Crossing the basement membrane
During transendothelial migration, neutrophils interact with endothelial cells. Interactions with CXCL1, ICAM-1 and PECAM-1 lead to the mobilization of VLA-3, VLA-6 and NE in a MST1- and Rab27a-dependent manner.
6.4 OUTLOOK

The results of the work presented expand our understanding of the underlying mechanisms by which endothelial cell interactions ‘educate’ neutrophils to penetrate the basement membrane. Huber et al. demonstrated that neutrophils only penetrate the BM in the presence of an overlying endothelium (Huber and Weiss, 1989). Furthermore, it was shown that interactions with endothelial PECAM-1, ICAM-1 and CXCL1 are required to overcome the BM (Wang et al., 2005). So far, no signaling molecules could be associated with this step. In this study, the serine/threonine kinase MST1 was identified as the first signaling molecule indispensable for neutrophil BM penetration into inflamed tissue. Furthermore, interactions of endothelial ICAM-1 and CXCL1 with β2 integrins on neutrophils could be associated with the exocytosis of NE, whereas interactions with endothelial PECAM-1 are important for the exocytosis of VLA-6. Whether ICAM-1/CXCL1 and/or PECAM-1 lead to the exocytosis of VLA-3 is not clear yet. In addition, the exact cooperation of the laminin-binding integrins VLA-3 and VLA-6 and the protease NE on neutrophils to penetrate the BM is also still unclear.

Since the basement membrane is essential for maintaining vascular integrity, significant degradation of the basement membrane is unlikely. Enormous numbers of neutrophils penetrate the BM, but leave the BM morphologically intact (Nourshargh and Alon, 2014, Rowe and Weiss, 2008, Hallmann et al., 2015). One of the hypothesis is that during transmigration, endothelial cell traction forces and/or surface-associated enzymatic activity might promote local reversible disassembly of the BM network and consequently increase local pore size to permit transmigration via a proteinase-independent process (Rowe and Weiss, 2008). This hypothesis is supported by Wang et al who showed that neutrophils seek for LER sites and that these sites are enlarged after IL-1β induced neutrophil transmigration (Wang et al., 2006). Only in rare cases, using an NE-fluorescent activatable substrate (NE680FAST), a high NE activity could be detected close to the abluminal site of postcapillary venules in TNF-α stimulated cremaster muscles. In addition, it could be demonstrated that a couple of transmigrated neutrophils were positive for laminin alpha 5 in TNF-α stimulated cremaster muscles. This is in line with results from other groups showing laminin alpha 5 positive...
transmigrated neutrophils in IL-1β stimulated cremaster muscles (Wang et al., 2006). Furthermore, neutrophils extravasate from so called ‘hot spots’ (Colom et al., 2015, Voisin et al., 2009, Weninger et al., 2014). Keeping that in mind, one could hypothesize that the first line of neutrophils penetrating the basement membrane enlarges LERs and drag some laminin fibers along with them.

Using an NE-fluorescent activatable substrate (NE680FAST) revealed a mild activity of NE on the surface of neutrophils interacting with the luminal site of venular endothelial cells in TNF-α stimulated cremaster muscles. This activity of NE is decreased in Mst1/− mice, although the number of rolling and adherent neutrophils is similar. Release of granules is regulated by a binary signal, one being adhesion dependent and the other involves the ligation and activation of immune receptors (Sengelov et al., 1995). As TNF-α activates neutrophils themselves in addition to the interaction between β2 integrins and endothelial ICAM-1, it is not surprising that at least a mild release of NE is triggered in these rolling and adherent neutrophils. Moreover, it was demonstrated that interactions with endothelial ICAM-1 and CXCL1 are sufficient to mobilize NE to the surface of neutrophils, a process dependent on MST1. A recent study by Colom et al. showed that neutrophil derived NE, mobilized to the cell surface in response to LTB4, bound to neutrophilic Mac-1 and was responsible for cleavage of JAM-C. This LTB4-NE-Mac-1 axis promotes neutrophil reverse TEM (Colom et al., 2015). It is tempting to speculate that NE promotes efficient TEM of neutrophils from postcapillary venules to the site of inflammation.

After neutrophils migrate through the endothelial layer, they are hypothesized to interact with matrix components of the BM via laminin binding β1 integrins, like VLA-3 and VLA-6, and β3 integrins. Extravasating neutrophils need to interact with ICAM-1 and PECAM-1 to induce the mobilization of vesicles containing laminin binding β1 integrins. This vesicle mobilization translocates laminin binding β1 integrins to the cellular surface, a prerequisite to pass the BM (Dangerfield et al., 2002, Wang et al., 2005). The result of this thesis demonstrate that MST1 is essential for the exocytosis of VLA-3 and VLA-6 as neutrophils from Mst1/− mice failed to translocate these proteins to the cell surface upon stimulation with PECAM-1/ ICAM-1/ CXCL1.
VLA-3 and VLA-6 seem to be regulated by cytokine dependent mechanisms. VLA-3 was shown to be necessary for neutrophil extravasation in TNF-α and fMLP-induced transmigration \textit{in vivo} (Hyun et al., 2012). Using blocking antibodies suggest a role for VLA-6 in IL-1β, but not TNF-α dependent neutrophils extravasation (Dangerfield et al., 2005). Interestingly, when using neutrophils deficient in the TNF receptor, blocking of PECAM-1 trapps neutrophil between the endothelial layer and the BM (Woodfin et al., 2009). This suggest different mechanisms to penetrate the basement membrane, dependent on the stimulus, which is either activating the endothelium only (e.g. IL-1β) or both the endothelium and the neutrophil (e.g. TNF-α).

Nevertheless, these results show that VLA-3, VLA-6 and NE are stored in distinct vesicles and are differently regulated. MST1 regulates the mobilization of all three, VLA-3, VLA-6 and NE, in response to PECAM-1, ICAM-1 and CXCL1 stimulation. Additionally, the distribution and translocation of Rab27a was disrupted in $\textit{Mst1}^{-/-}$ neutrophils. From these experiments we cannot conclude whether Rab27a is responsible for the mobilization of only one or all vesicles, containing VLA-3, VLA-6 and NE. It is very likely that Rab27a at least controls the translocation of NE containing vesicles, as demonstrated by the group of Sergio Catz (Catz, 2013). Further studies are required to define the exact involvement of Rab27a during the translocation of VLA-3, VLA-6 and NE during vesicle trafficking. Moreover, it would be intriguing to discover the specific function of Rab27a-controlled vesicle trafficking for neutrophil function \textit{in vivo}. Rab27a is the only Rab associated with a human disease, called Griscelli syndrome type 2 (GS2), where patients suffer from often fatal viral and bacterial infections, due to severe immunodeficiency including neutropenia.

Rab GTPases are controlled by Rab effector proteins. So far, two Rab27a effector proteins, Slp1/JFC1 and Munc13-4, could be associated with impaired release of granules in neutrophils. It would be exciting to explore if Slp1/JFC1 and/or Munc13-4 regulate the translocation of VLA-3, VLA-6 and NE. As MST1 influences LFA-1 containing vesicle trafficking in T cells by regulating the Rab13 effector DENND1C (Nishikimi et al., 2014), it is tempting to speculate that MST1 is involved in the vesicle transport of neutrophils by controlling the activity of the Rab27a effector proteins,
Slp1/JFC1 and Munc13-4. Further experiments are necessary to explore these possibilities.

Defining the exact function of MST1 will contribute to a better understanding of the underlying defects in patients suffering from STK4 deficiency. Recently, Lerman et al. reported that VLA-3 is upregulated in neutrophils in human septic patients and in septic mice (Lerman et al., 2014). Neutrophils with an increased expression of VLA-3 displayed a hyperinflammatory phenotype and blocking VLA-3 on neutrophils in septic mice improved their survival (Lerman et al., 2014). It would be interesting to outline the involvement of MST1 and reveal if MST1 could modulate the inflammatory phenotype during sepsis.

Taken together, we demonstrate that the serine/threonine-kinase MST1 is indispensable for neutrophil penetration of the basement membrane by regulating the mobilization of VLA-3, VLA-6 and NE from intracellular vesicles to the plasma membrane. These findings emphasize the importance of MST1 for early innate immune responses and also helps to understand the phenotype of recurring infections found in patients suffering from STK4 immune deficiency.

9 ACKNOWLEDGMENTS

During my PhD study, I benefited from the knowledge, support, helpful discussions, advices and collaboration of many excellent researchers and colleagues around me in the Walter Brendel Center for Experimental Medicine and especially in the SFB914. This thesis would not have been possible without the help and support and I would like to express my sincere gratitude.

First of all, I would like to thank my supervisor Prof. Dr. med. Markus Sperandio for giving me the opportunity to study this intriguing project. I would like to thank him for his supervision, encouragement, enthusiasm and support during the entire period of my PhD study. Importantly, he gave me the freedom to follow my own ideas.

Second, I want to thank my thesis advisory committee, Prof. Dr. rer. nat. Kirsten Lauber, PD Dr. rer. nat. Markus Moser and PD Dr. rer. physiol. Melanie Laschinger for fruitful discussions and very helpful brainstorming.

Third, I am specially and truly thankful to Dr. rer. nat. Monika Prünster for her invaluable supervision and constant support throughout my entire PhD thesis. I really learned a lot from her in many aspects.

I would like to acknowledge the SFB914 and the associated IRTG for excellent professional training to broaden my horizon and for funding. A special ‘thank you’ goes to Dr. rer. nat. Verena Kochan, for helping me to manage the bureaucracy.

I especially have to thank both, Dr. rer. nat. Monika Prünster and Dr. rer. nat. Ina Rohwedder for incredible insightful brainstorming and intensive discussions about everything during my PhD study.

Thank you to all group members, Roland Immler M.Sc., Dr. rer. nat. Kristina Heinig, Dr. med. Andreas Margraf, Dr. med. Claudia Nussbaum and also the students, Johannes
R. Wiessner and Gabriel Gouveia for the support, advice and good atmosphere. I also want to extend my thanks to all the members of the Walter Brendel Center. It is a pleasure working with you.

Furthermore, I would like to thank Susanne Bierschenk and Nadine Schmidt for excellent technical assistance, administrative support and for their help with experiments.

I also want to thank PD Dr.rer.nat. Steffen Dietzel, for introducing and helping me with the multi photon laser scanning microscope.

Last but not least I want to thank my family. I’m especially grateful to my mother, Christina Fischer-Titz. Thank you for your support, without you I would have never gotten to this point. And to Michael Forsthuber, thank you for your never ending support, encouragement and patience.

Abstract: 139 words
Length: 9029 words
Running title: MST1 and neutrophil transmigration
Abstract
Neutrophils need to penetrate the perivascular basement membrane for successful extravasation into inflamed tissue, a process only incompletely understood. Here, we show that mammalian sterile 20-like kinase 1 (MST1) is a critical regulator of neutrophil extravasation during inflammation. We observed that Mst1-deficient (Mst1−/−) neutrophils persisted between the endothelium and the basement membrane of inflamed murine cremaster muscle venules, unable to migrate into the inflamed tissue. Mst1−/− neutrophils also failed to extravasate from gastric submucosal vessels in a murine Helicobacter pylori infection model. Mechanistically, impaired extravasation of Mst1−/− neutrophils was accompanied by defective translocation of VLA-3, VLA-6, and neutrophil elastase from intracellular vesicles to the neutrophil surface, a requirement for neutrophils to penetrate the basement membrane. Together, these findings highlight an unexpected role of MST1 in neutrophil extravasation and explain the severe immune defect observed in patients with MST1 deficiency.
Introduction
Recruitment of neutrophils from the intravascular compartment to sites of inflammation is a fundamental process during the innate immune response. The process follows a well-defined cascade of events, including neutrophil capture and rolling, firm adhesion, crawling, extravasation and migration into inflamed tissue (Nourshargh and Alon, 2014). Although most of the recruitment steps have been thoroughly studied in the past (Kolaczkowska and Kubes, 2013), the precise mechanism of neutrophil transmigration across venular walls and penetration of the perivascular basement membrane (BM) remain elusive (Hallmann et al., 2015, Rowe and Weiss, 2008, Sorokin, 2010, Muller, 2016). Once neutrophils have migrated through the endothelial layer, they are primed for subsequent penetration of the endothelial BM (Bixel et al., 2010, Thompson et al., 2001, Wegmann et al., 2006) at sites that express low levels of laminin 511 (Sixt et al., 2001, Wu et al., 2009, Kenne et al., 2010) and potentially also low levels of collagen IV (Wang et al., 2006). So far, it is known that the surface expression of VLA-3 (α3β1, CD49c/CD29) (Hyun et al., 2012) and VLA-6 (α6β1, CD49f/CD29) (Dangerfield et al., 2005), extracellular matrix binding integrins on neutrophils, are required for migration into inflamed tissue. VLA-3 was shown to be necessary for neutrophil extravasation in TNF-α and fMLP-induced transmigration in vivo (Hyun et al., 2012), while studies using blocking antibodies suggest a role for VLA-6 in IL-1β, but not TNF-α dependent neutrophil extravasation (Dangerfield et al., 2005). Migration through the BM was described to be further accompanied by the surface expression of the serine protease neutrophil elastase (NE) (Wang et al., 2005), although experiments using NE deficient mice in vivo could not confirm a role in the extravasation process (Young et al., 2007). Since VLA-3, VLA-6 and NE are stored in intracellular vesicles (Uriarte et al., 2008, Wang et al., 2005), they need to be translocated to the cell surface during transmigration.

Recently, three independent groups identified a novel human primary immunodeficiency disorder, caused by autosomal recessive loss of function mutation in the serine/threonine protein kinase 4 (STK4), which encodes MST1, the mammalian homolog of the Drosophila melanogaster kinase Hippo. Children with STK4 deficiency display recurring bacterial, viral and fungal infections together with autoimmune disease. They also suffer from lymphopenia, which explains part of the clinical manifestations.
However, their impaired response to acute bacterial infections, also suggests a defect in myeloid cell function. (Abdollahpour et al., 2012, Crequer et al., 2012, Nehme et al., 2012)

Studies using *Mammalian Ste-20 like kinase 1 (Mst1)* deficient mice showed that the ubiquitously expressed serine/threonine kinase MST1 is involved in lymphocyte trafficking by controlling exocytosis and localization of the β2 integrin Lymphocyte Function-associated Antigen-1 (LFA-1, CD11a/CD18, αLβ2) to the plasma membrane. MST1 associates via RAPL with the cytoplasmic tail of the αL subunit and leads to the translocation of LFA-1 containing vesicles in a DENND1C-Rab13 dependent manner (Nishikimi et al., 2014). The absence of MST1 in lymphocytes leads to adhesion as well as migration defects, resulting in impaired lymphocyte trafficking and a decreased number of peripheral lymphocytes (Katagiri et al., 2006, Katagiri et al., 2009). To investigate the role of MST1 for myeloid cell function, we evaluated neutrophil recruitment in *Mst1*−/− mice under *in vivo* and *in vitro* conditions. We show that MST1 is dispensable for LFA-1 dependent neutrophil adhesion in mice and humans, but critical for neutrophil extravasation into the interstitial space through controlling translocation of VLA-3, VLA-6 and neutrophil elastase (NE) to the neutrophil surface. Hence, we identify MST1 deficiency as a neutrophil transmigration deficiency with a basement membrane penetration defect.
Results

MST1 is dispensable for neutrophil adhesion but critical for extravasation

In the past, conflicting results on the expression of MST1 in mouse neutrophils were published (De Souza et al., 2002). Therefore, we first confirmed the expression of MST1 in neutrophils from wild type (WT) and the absence of MST1 in Mst1−/− neutrophils (Figure 1A). In addition, we also tested for MST2 and did not detect any MST2 expression neither in WT nor in Mst1−/− neutrophils (Figure 1A and Supplemental Figure 1A). Next, we determined differential cell counts of peripheral blood and in accordance to previously published data (Choi et al., 2009) found decreased numbers of lymphocytes in Mst1−/− mice compared to WT mice (Figure 1B). In contrast, neutrophil counts were not significantly altered in Mst1−/− mice compared to WT mice.

Previous studies had shown that MST1 is crucial for β2 integrin LFA-1 (αLβ2)-dependent T-cell adhesion (Katagiri et al., 2006). To test whether LFA-1 dependent adhesion is also affected in neutrophils lacking MST1, we compared neutrophil adhesion efficiency in TNF-α stimulated cremaster muscle venules of WT and Mst1−/− mice using intravital microscopy. Unexpectedly, we observed no difference in neutrophil adhesion efficiency between WT and Mst1−/− mice (Figure 1C). In addition, neutrophil rolling flux fraction and neutrophil rolling velocity, which is regulated by LFA-1, were not altered in Mst1−/− mice compared to WT mice (Supplemental Figure 1B and C). We then performed ex vivo flow chamber assays using glass capillaries coated with various combinations of adhesion molecules and found no difference in the number of adherent leukocytes (Figure 1D). Furthermore, Mst1−/− neutrophils displayed proper LFA-1 reorganization and accumulation at the uropod during postarrest modifications as observed in flow chambers using confocal microscopy (Figure 1E and Supplemental Video 1A,B). Neutrophil surface expression of LFA-1, Mac-1, CXCR2, CD44, PSGL1 and CD62L were similar in WT and Mst1−/− mice (Supplemental Figure 1D). In addition, CXCL1 dependent LFA-1 activation in a soluble ICAM-1 binding assay were similar between neutrophils isolated from WT and Mst1−/− mice (Supplemental Figure 1E,F).

Next, we investigated neutrophil adhesion from two human patients with STK4 (also known as MST1) deficiency and their heterozygous parents (Abdollahpour et al., 2012). For this approach, we determined the number of adherent neutrophils/FOV in flow
chambers coated with E-selectin/ICAM-1/CXCL8. The number of adherent neutrophils/FOV of STK4+/− patients was similar to adhesion observed for chambers perfused with neutrophils from their heterozygous (STK4+/−) parents (Figure 1F).

We then went on and asked whether MST1 deficiency could have any impact on neutrophil extravasation in a TNF-α induced peritonitis model. In WT mice, i.p. injection of TNF-α dramatically increased the number of neutrophils in the peritoneum compared to NaCl control injection. In contrast, neutrophils from Mst1−/− mice failed to transmigrate into the peritoneal cavity within 2h hours of TNF-α stimulation (Figure 1G).

Taken together, these in vitro and in vivo results demonstrate that, in contrast to T-cells, MST1 is dispensable for LFA-1 activation and clustering in neutrophils. Hence, neutrophil adhesion is unaffected in Mst1−/− mice as well as in patients with STK4 deficiency. However, we could detect a massive decrease in the number of extravasated neutrophils in the peritoneal lavage of Mst1−/− mice compared to WT mice in the TNF-α induced peritonitis model suggesting a neutrophil recruitment defect downstream of intravascular adhesion.

**Loss of MST1 in neutrophils results in decreased transmigration in vivo**

Using multi-photon laser scanning microscopy we next investigated neutrophil transmigration 180 to 240 min after intrascrotal injection of TNF-α, together with a non-blocking antibody against PECAM1 (Woodfin et al., 2011), into Lyz2GFP (Faust et al., 2000) and Mst1−/− x Lyz2GFP mice, where neutrophils are endogenously labeled with EGFP. We observed an increasing number of neutrophils in Lyz2GFP mice crossing postcapillary venules and migrating into the inflamed tissue (Figure 2A, upper panel and Supplemental Video 2A). In contrast, neutrophils from Mst1−/− x Lyz2GFP mice remained close to the abluminal part of the vessel wall (Figure 2A, lower panel and Supplemental Video 2B). We then determined the duration of neutrophil transmigration into tissue and observed that transmigration of Lyz2GFP mice required 7.5 ± 0.8 min (median ± SEM), which is similar to the time reported by others (Woodfin et al., 2011). In contrast, most neutrophils of Mst1−/− x Lyz2GFP mice failed to transmigrate into tissue within the 20 min of observation (20 ± 0.8 min, median ± SEM) (Figure 2B) and accumulated at the abluminal site of postcapillary venules (Figure 2C).
To test, whether further inflammatory stimulation could induce migration into the interstitial matrix, a laser injury near postcapillary venules was set 3 h after TNF-α stimulation. Neutrophils of Lyz2GFP mice swarmed and accumulated at the site of laser injury within 30 min, as described by Lämmermann et al. (Lammermann et al., 2013). Interestingly, neutrophils deficient in MST1 remained at the abluminal site of venules and were unable to interstitially migrate to the site of laser injury (Figure 2D,E and Supplemental Video 3A,B). However, absent interstitial migration was not due to an intrinsic migration defect of Mst1−/− neutrophils as migration of bone marrow-derived neutrophils to fMLP or CXCL1 in a 3D collagen gel assay was not affected by the absence of MST1 (Supplemental Figure 2A,B), indicating that interstitial migration is independent of MST1.

**MST1 deficient neutrophils fail to transmigrate to the site of infection in a Helicobacter pylori mouse infection model**

Next, we evaluated the role of MST1 in a murine *Helicobacter pylori* (*H. pylori*) infection model. Previous work had shown that neutrophils play an important role in the pathogenesis of *H. pylori* infection (D'Elios et al., 2007). The bacterium induces a strong inflammatory response in the gastric mucosa, which is dependent on the *H. pylori* neutrophil-activating protein (HP-NAP). Furthermore, pro-inflammatory cytokines such as CXCL8 are secreted during the inflammatory process, recruiting additional neutrophils and monocytes to the site of inflammation (Montecucco and Rappuoli, 2001). We infected WT and *Mst1*−/− mice with *H. pylori* orogastrically and sacrificed the mice 3 months later. As reported earlier (Suerbaum and Michetti, 2002), the majority of infiltrated neutrophils were found in the antrum region of the stomach (Figure 3A upper panel). In contrast, we only detected a very small number of neutrophils in the gastric epithelium of the antrum of *Mst1*−/− mice (Figure 3A lower panel) demonstrating reduced neutrophil extravasation (Figure 3B). In line with this, the number of colony forming units (cfu) of *H. pylori* in the antrum showed a significant increase in *Mst1*−/− mice compared to WT mice (Figure 3C), indicating a more successful colonization.

Finally, we immunostained tissue sections from the lower part of the mucosa, where neutrophils extravasate from postcapillary venules (Figure 3D). We did not observe any difference in the number of total neutrophils/FOV between WT and *Mst1*−/− mice (Figure
3E). However, in WT mice neutrophils migrated from venules into the inflamed tissue, while, as expected, neutrophils from Mst1<sup>−/−</sup> mice remained near the vessel wall (Figure 3F). Thus, MST1 is required for proper neutrophil extravasation from the submucosal vasculature into tissue during H. pylori infection.

**MST1 is essential for neutrophils to penetrate the basement membrane**

Next, we focused on the capacity of Mst1<sup>−/−</sup> neutrophils to penetrate the perivascular BM. To this end, we performed whole mount stainings of TNF-α stimulated cremaster muscles using antibodies against laminin α5 (LNα5), endothelial cell-specific adhesion molecule 1 (ESAM1) to visualize the BM and endothelial cell contacts, and anti-MRP14 to identify neutrophils (Figure 4A). By means of confocal microscopy, neutrophils were classified into three groups according to their position during the extravasation from postcapillary venules. Neutrophils, embedded within the endothelial layer belonged to position I. Position II represented neutrophils located between the endothelium and BM and fully transmigrated neutrophils were classified as being in position III (Figure 4B) (Bixel et al., 2010). Neutrophils of WT and Mst1<sup>−/−</sup> mice were present at similar percentages embedded within the endothelium (position I). However, significantly more Mst1<sup>−/−</sup> neutrophils were located between the endothelium and the BM (position II) compared to WT neutrophils while significantly more WT than Mst1<sup>−/−</sup> neutrophils were fully transmigrated (position III) (Figure 4C).

To gain further insights into the molecular mechanisms of MST1 dependent transmigration, we performed transwell assays where filters were coated with BSA (control), laminin, a key component of the BM, alone (Yousif et al., 2013), or with PECAM-1 and ICAM-1, while CXCL1 was used as chemoattractant. Laminin alone did not induce transmigration of neither WT nor Mst1<sup>−/−</sup> neutrophils. A combination of laminin, PECAM-1 and ICAM-1 efficiently induced transmigration along a CXCL1 gradient, however only for WT but not for Mst1<sup>−/−</sup> neutrophils (Figure 4D). In line with this, Mst1<sup>−/−</sup> neutrophils failed to transmigrate as efficiently as WT neutrophils through filters containing a monolayer of mouse endothelial 1G11 cells in response to CXCL1 (Figure 4E). Importantly, we did not find differences in transmigrated WT and Mst1<sup>−/−</sup> neutrophils in transwell assays without coating (Figure 4F), implying that MST1 is essential for neutrophils to penetrate the BM in vivo and in vitro.
MST1 is required for the translocation of VLA-3, VLA-6 and NE to the cell surface

It had been shown previously, that mobilization of VLA-3, VLA-6 and NE from intracellular stores to the plasma membrane is a crucial step for successful neutrophil transmigration (Hyun et al., 2012, Lerman et al., 2014, Wang et al., 2005). In order to evaluate the putative role of MST1 in the mobilization of VLA-3, VLA-6 and NE, neutrophils from WT or Mst1⁻/⁻ mice were seeded on slides coated with BSA or PECAM-1/ICAM-1/CXCL1 and immunostained with antibodies against VLA-3, VLA-6 or NE. Confocal microscopy showed that WT as well as Mst1⁻/⁻ neutrophils seeded on BSA displayed all three molecules - VLA-3, VLA-6 and NE (Supplemental Figure 3D,G) - within intracellular stores. Fluorescence intensity profiles (see Materials and Methods and Supplemental Figure 3A) of VLA-3, VLA-6 and NE were similar between WT and Mst1⁻/⁻ cells seeded on BSA (Supplemental Figure 3B-D). PECAM-1/ICAM-1/CXCL1 coating induced the translocation of VLA-3, VLA-6 and NE to the surface of interacting WT neutrophils, leading to a ring-like structure at the cell border (Figure 5A-I). In contrast, neutrophils derived from Mst1⁻/⁻ mice failed to efficiently mobilize any of the three proteins to the cell surface, resulting in less pronounced ring formation in Mst1⁻/⁻ neutrophils (Figure 5A-I). Of note, western blot analysis showed no difference in the total protein levels of VLA-3, VLA-6 and NE between WT and Mst1⁻/⁻ neutrophils (Supplemental Figure 3E).

In order to verify MST1-dependent mobilization in vivo, we investigated NE activity with an NE-fluorescent activatable substrate (NE680FAST) in postcapillary venules of unstimulated and TNF-α stimulated cremaster muscle whole mounts from WT and Mst1⁻/⁻ mice. In unstimulated venules of WT mice we were unable to detect any NE activity, while 2h after TNF-α stimulation NE activity could be observed (Figure 5J). TNF-α stimulated venules from Mst1⁻/⁻ mice showed decreased NE activity as compared to WT mice (Figure 5J). Importantly, the number of adherent cells was similar in WT and Mst1⁻/⁻ mice (Supplemental Figure 3F). Taken together, these in vitro and in vivo results demonstrate that MST1 is indispensable for efficient translocation of VLA-3, VLA-6 and NE to the surface of neutrophils.
MST1 translocates with Rab27a to the plasma membrane

Rab27a is a central regulator of vesicle trafficking in neutrophils (Catz, 2014, Sheshachalam et al., 2014). Therefore, we investigated Rab27a translocation to the plasma membrane in response to PECAM-1/ICAM-1/CXCL1-stimulation. Rab27a displayed an intracellular localization in WT and Mst1−/− neutrophils when seeded on BSA (Figure 6A and Supplemental Figure 4A). In WT neutrophils, PECAM-1/ICAM-1/CXCL1-coating induced the translocation of Rab27a to the plasma membrane (Figure 6A,B) and led to ring formation of Rab27a in most of analyzed WT neutrophils (Figure 6C). In contrast, neutrophils derived from Mst1−/− mice failed to translocate Rab27a to the plasma membrane in response to PECAM-1/ICAM-1/CXCL1 stimulation (Figure 6A-C). However, total protein levels of Rab27 were similar between WT and Mst1−/− neutrophils (Supplemental Figure 4B).

Next, we investigated whether MST1 itself translocates to the plasma membrane upon ICAM-1/PECAM-1/CXCL1 stimulation. MST1 displayed intracellular localization in WT neutrophils seeded on BSA (Figure 6D-F). In response to ICAM-1/PECAM-1/CXCL1 stimulation, MST1 localized together with Rab27a at the plasma membrane (Figure 6D-F).

Taken together, these results demonstrate that Rab27a and MST1 translocate to the cellular membrane upon ICAM-1/PECAM-1/CXCL1 stimulation, implying a role of MST1 in Rab27a-dependent vesicle transport.
Discussion

In this study, we identify the serine/threonine kinase MST1 as the first signaling molecule indispensable for neutrophil basement membrane penetration into inflamed tissue.

Originally, MST1 (mammalian homolog of the Drosophila Hippo protein) was identified in Drosophila melanogaster as the central constituent of the Hippo pathway, controlling organ size and proliferation. Recently, MST1 has attracted more attention due to its role in cancer development (Yu et al., 2015) and the discovery that a mutation in human STK4 (Mst1) leads to a primary immune deficiency. Patients with a deficiency in STK4 present with recurring bacterial, fungal and viral infections, and display lymphopenia and intermittent neutropenia (Abdollahpour et al., 2012, Crequer et al., 2012, Nehme et al., 2012). Using Mst1−/− mice, MST1 was shown to be required for LFA-1 dependent T-cell trafficking (Katagiri et al., 2009, Ueda et al., 2012) by regulating the transport and distribution of LFA-1 containing vesicles to the plasma membrane and subsequent LFA-1 clustering and adhesion of T-cells (Katagiri et al., 2006).

We demonstrate, that in contrast to T-cells (Katagiri et al., 2009), MST1 is dispensable for LFA-1-dependent neutrophil adhesion in mice and humans. Neutrophils from Mst1−/− mice showed no defect in LFA-1 activation. In addition, clustering of LFA-1 as well as static adhesion on ICAM-1 coated surfaces was not altered in Mst1−/− neutrophils compared to WT neutrophils. Murine Mst1−/− neutrophils as well as neutrophils derived from two patients with STK4 deficiency adhered to E-selectin/ICAM-1/CXCL1 coated flow chambers to the same extent as WT controls or their heterozygote parents, respectively. These results suggest that different mechanisms of LFA-1 regulation/activation exist between lymphocytes and neutrophils. This may be supported by data from Fabbri et al., reporting that Rab11, is required for the trafficking of LFA-1-containing vesicles in neutrophils (Fabbri et al., 2005). In T-cells, Rap13 is responsible for this step (Nishikimi et al., 2014).

Although Mst1−/− neutrophils showed no defective adhesion in our studies, they failed to extravasate into the peritoneal cavity. In TNF-α stimulated cremaster muscles, Mst1−/− neutrophils remained in close contact with the abluminal side of the vessel. Even after additional stimulation by inducing a laser injury next to the vessel, Mst1−/− neutrophils persisted at the vessel wall and failed to migrate to the site of injury. After
crossing the endothelial cell layer, neutrophils have to penetrate the underlying BM (Hallmann et al., 2015, Sorokin, 2010, Wang et al., 2006). The BM of post-capillary venules is mainly composed of laminin 411 (α4β1γ1 laminin subunit), laminin 511 (α5β1γ1 laminin subunit) and type IV collagen (Sorokin, 2010). Although many studies have been performed on leukocyte adhesion and TEM, the mechanism by which neutrophils penetrate the BM is still poorly understood (Rowe and Weiss, 2008, Hallmann et al., 2015).

Previous studies showed that genetic, antibody or inhibitor-mediated blockade of PECAM-1 (Wang et al., 2005), VLA-3 (Hyun et al., 2012), VLA-6 (Dangerfield et al., 2002, Dangerfield et al., 2005, Wang et al., 2005) or NE (Wang et al., 2005) leads to an arrest of infiltrating neutrophils between the endothelial layer and the underlying BM. Extravasating neutrophils need to interact with ICAM-1 and PECAM-1 to induce the mobilization of vesicles containing VLA-6 and NE. This mobilization translocates VLA-6 and NE to the cellular surface, a prerequisite to pass the BM (Dangerfield et al., 2002, Wang et al., 2005). We found that MST1 is essential for the exocytosis of VLA-3, VLA-6 and NE as neutrophils from Mst1<sup>-/-</sup> mice failed to translocate these proteins to the cell surface upon stimulation with PECAM-1/ ICAM-1/ CXCL1. In contrast to WT neutrophils, neutrophils from Mst1<sup>-/-</sup> mice failed to pass through a PECAM-1, ICAM-1 and laminin-coated transwell filter in an in vitro transmigration assay.

As MST1 influences LFA-1 clustering in T-cells by regulating LFA-1 containing vesicle trafficking via Rab13 (Nishikimi et al., 2014), we hypothesized, that MST1 is similarly involved in the mobilization of the vesicles containing VLA-3, VLA-6 and NE to the plasma membrane in neutrophils. The GTPase Rab27a is a master regulator of exocytosis in neutrophils (Catz, 2014). Several studies indicate that Rab27a and its effectors JFC1 (synaptotagmin-like protein 1) and Munc13-4 regulate the secretion of azurophilic granules, containing NE and MPO (Brzezinska et al., 2008, Munafo et al., 2007). We discovered that Rab27a and MST1 itself translocate to the plasma membrane in response to PECAM-1/ ICAM-1/CXCL1. However, translocation of Rab27a is defective in Mst1<sup>-/-</sup> neutrophils indicating that MST1 is involved in Rab27a dependent vesicle trafficking. Further studies may elucidate, whether Rab27a regulates only NE secretion or is furthermore involved in VLA-3 and VLA-6 translocation.
Taken together, we demonstrate that the serine/threonine-kinase MST1 is indispensable for neutrophil penetration of the basement membrane by regulating the mobilization of VLA-3, VLA-6 and NE from intracellular vesicles to the plasma membrane. These findings elucidate the importance of MST1 for early innate immune responses and also explain the phenotype of recurring infections found in patients suffering from \textit{STK4} immune deficiency.
Methods

Study approval

*Mst1*−/− mice were generated by Dae Sik Lim as described (Oh et al., 2009). *Lyz2 GFP* (Faust et al., 2000) were generously provided by Thomas Graf, Centre for Genomic Regulation, Barcelona, Spain. *Lyz2 GFP* x *Mst1*−/− were generated by crossbreeding. C57BL/6 wild type (WT) mice were obtained from Janvier Labs. Animal studies were approved by the Regierung von Oberbayern, Germany, AZ 55.2-1-54-2531-149/10 and AZ 55.2-1-54-2532-34/14. Human studies with purified neutrophils from parents (*STK4*/+) or *STK4*−/− patients were approved by the ethical committee, LMU, Germany, AZ 66-14.

Western Blot

Isolated neutrophils were incubated in lysis buffer (1x PBS, 1% Triton X-100 (Applichem), 0.5% Na deoxycholate, 0.1% SDS supplemented with protease (Roche) and phosphatase inhibitors (Sigma)), homogenized in Laemmli sample buffer and boiled for 5min. Proteins were resolved by SDS–polyacrylamide gel electrophoresis (SDS–PAGE) and then electrophoretically transferred onto PVDF membranes, which were subsequently incubated with antibodies. The following antibodies were used: rabbit anti-MST1 antibody (Upstate), rabbit anti-MST2 antibody (Cell Signaling), rabbit anti-NE antibody (Abcam), mouse anti- VLA-3 antibody (42/CD49c, BD), rabbit anti- VLA-6 antibody (Thermo Scientific), sheep anti- Rab27a (R&D), mouse anti-GAPDH antibody (Calbiochem), goat anti-mouse HRP, goat anti-rabbit HRP or donkey anti-sheep HRP (Jackson ImmunoResearch). Bound antibodies were detected using enhanced chemiluminescence (Millipore Corporation).

Intravital microscopy of TNF-α stimulated mouse cremaster muscle venules

Intravital microscopy of mouse cremaster muscle venules was performed in WT and *Mst1*−/− mice, as previously described (Pruenster et al., 2015). Briefly, 2 h after intrascrotal injection of TNF-α (R&D systems, 500 ng/mouse) a carotid artery catheter was placed for blood sampling (ProCyte Dx, IDEXX Laboratories). Thereafter, the cremaster muscle was exteriorized and rolling flux fraction (rolling cell/min divided by total neutrophil flux), rolling velocity and leukocyte adhesion efficiency (number of
adherent cells/mm divided by the systemic neutrophil count) determined by intravital microscopy (Olympus BX51WI microscope, water immersion objective 40x, 0.80 NA, Olympus; CCD camera, CF8/1, Kappa). Postcapillary venules ranged from 20-40 μm in diameter.

**Murine ex vivo flow chamber system and LFA-1 clustering**

To investigate adhesion under flow conditions, we used a previously described flow chamber system (Yang et al., 2012). Glass capillaries (Rect.Boro Capillaries 0.04 x 0.40 mm ID VitroCom, Mountain Lakes, USA) were coated with E-selectin (R&D systems, 20 μg/ml), ICAM-1 (R&D Systems, 15 μg/ml) and/ or CXCL1 (Peprotech, 15 μg/ml). Flow chambers were autoperfused with whole blood from WT or Mst1−/− mice via a carotid artery catheter. One representative field of view was recorded by intravital microscopy (water immersion objective x20, 0.95 NA, Olympus). In order to investigate LFA-1 clustering during neutrophil adhesion under flow conditions, flow chambers were perfused (2 µl/min) with whole blood from WT or Mst1−/− mice, incubated with rat anti-LFA-1 Alexa Fluor 546 antibody (2D7, BioLegend). Adherent cells were imaged using confocal microscopy (Leica System SP5, 63x, 1.4 NA oil objective).

**Human flow chamber system**

In order to investigate adhesion of human neutrophils under flow conditions we used a previously described flow chamber system (Nussbaum et al., 2013). Glass capillaries (Rect.Boro Capillaries 0.2 x 2 mm ID VitroCom, Mountain Lakes, USA) were coated with combinations of E-selectin (R&D systems, 5 μg/ml), ICAM-1 (R&D Systems, 4 μg/ml) and CXCL8 (Peprotech, 5 μg/ml). Flow chambers were perfused (2 dyne/cm²) with Ficoll purified neutrophils (2x10⁵/ml) from parents (STK4+/+) or STK4−/− patients.

**Surface expression of LFA-1, Mac-1, CXCR2, CD44, PSGL1 and CD62L**

Surface expression of αL (LFA-1, CD11a- APC, M17/4, eBioscience), αM (Mac-1, CD11b - Brilliant Violet 570, M1/70, BioLegend), CXCR2 (CD182- APC, 242216, R&D), CD44 (CD44- Brilliant Violet 570, IM7, BioLegend), PSGL1 (CD162- PE, 2PH1, Pharmingen) und L-selectin (CD62L- FITC, MEL-14, BioLegend) of bone marrow derived Ly6G+ (Ly6G-Pacific Blue, 1A8, BioLegend) neutrophils from WT and Mst1−/−
mice was compared using a Beckman Coulter Gallios™ flow cytometer and analyzed using Kaluza® Flow Analysis Software (Beckman Coulter).

Soluble ICAM-1 binding assay
Soluble ICAM-1 binding assay was performed as described previously (Pruenster et al., 2015). Briefly, bone marrow derived neutrophils were isolated from WT and Mst1−/− mice using a Percoll gradient (Sigma). Cells were suspended in complete HBSS buffer (Hanks Balanced Salt Solution containing 0.1% Glucose, 1 mM CaCl₂ and MgCl₂, 0.25% BSA (GE healthcare) and 10 mM Hepes (Sigma), pH7.4). Cells were stimulated with 100 ng/ml rmCXCL1 (Peprotech) or an equal volume of HBSS buffer, in the presence of rmICAM-1 (ICAM-1 hFc chimera, R&D Systems, 20µg/ml), goat anti-human Fc gamma-biotin (polyclonal, eBioscience) and Streptavadin – PerCP-Cy5.5 (eBioscience) for 3 min at 37°C. Cells were fixed (FACS Lysing Solution, BD), stained with rat anti-mouse Ly6G-Pacific Blue antibody (1A8, BioLegend) and measured using flow cytometer.

TNF-α induced neutrophil extravasation into the peritoneal cavity
WT and Mst1−/− mice were intraperitoneally injected with NaCl (control) or TNF-α (rmTNF-α, R&D Systems, 1 µg/mouse). Mice were sacrificed 2 h later, and peritoneal lavage was performed, cells were collected, stained with a rat anti- Ly6G (1A8, BioLegend) and the number of extravasated neutrophils was evaluated using rat anti-Ly6G antibody (1A8, BioLegend), Flow-Count™ Fluorospheres and flow cytometry.

Multi photon microscopy of the mouse cremaster muscle
Extravasation of neutrophils into inflamed mouse cremaster muscle of Lyz2GFP and Lyz2GFP x Mst1−/− mice was investigated by multi photon microscopy (Woodfin et al., 2011). Briefly, TNF-α (R&D Systems, 500 ng) and a rat anti-PECAM-1 antibody Alexa Fluor 546 (390, BioLegend; 3 µg) were injected into the scrotum of mice. 1 h later, the cremaster muscle was prepared for intravital multi photon microscopy. Z-stacks were captured using a TrimScope (LaVision Bio Tec (Rehberg et al., 2011), upgraded with Hamamatsu H7422A-40 high sensitivity GaAsP photomultipliers; Olympus XLUMPlanFl, 20x, 0.95 W objective, 810 nm excitation, ultra-sensitive port (USP) 525/50, 580/60). Images (966 x 966 pixels, 300 x 300 µm, step size 4 µm) were acquired at intervals of
30 seconds. After acquisition, images were processed and analyzed using Imaris 7 (Bitplane). Transmigration time was defined from the point the cells started to transmigrate (excluding intraluminal crawling) until they completely detached from the abluminal vascular wall.

**Laser induced injury using multi photon microscopy in the mouse cremaster muscle**

A laser injury using high laser power by scanning an area of 50 x 50 µm 121 times in the center of 500 x 500 µm was set, 3 h after intrascrotal injection of rmTNF-α and anti PECAM1- Alexa Fluor 546 antibody. Images were acquired for 30 min as described above. The GFP intensity, which is proportional to the number of neutrophils at the site of injury, was analyzed using Fiji software.

**Chemotaxis assay for neutrophils in 3D collagen gels**

3D Chemotaxis was performed according to the manufacturer’s instructions (Ibidi). Briefly, bone marrow derived neutrophils from WT and Mst1−/− mice were isolated using a Percoll gradient and 3x10^5 cells were seeded together with Collagen I into a channel of Ibidi µ- Slides Chemotaxis3D. After 5 min of incubation at 37 °C, the reservoirs were filled with either complete HBSS-buffer alone or with rmCXCL1 (Peprotech, 100 ng/ml) or fMLP (Sigma, 10 µM). Images were acquired every 14 s for 30 min at 37 °C using an Axiovert 200M microscope. Images were analyzed using Fiji software.

**Helicobacter pylori infection model**

WT or Mst1−/− mice were infected with the *H. pylori* strain PMSS1wt orogastrically three times with 10^9 bacteria or sterile Brucella Broth (BB) alone as a control. Animals were sacrificed after 6 weeks or 3 months. Stomachs were opened washed with PBS and divided into two equal halves. One half was homogenized and appropriate dilutions were spread on selective serum plates (GC agar Difco with horse serum (80 ml/l), IsoVitaleX™ (10 ml/l; BD, Germany), nalidixic acid (5 g/l), bacitracin (50 g/l), DENT (Oxoid). The number of cfu was calculated per gram of gastric tissue. The other half of the stomach was fixed in Tissue-Tek® O.C.T™ Compound (Sakura), stained with a primary rat anti-Ly6G antibody (BD Pharmingen) and detected using a goat anti-rat
Alexa Fluor 555 antibody (Invitrogen) together with DAPI (Sigma). Images were obtained using an Olympus fluorescence microscope (10x, 0.40 NA dry objective). In a second set of experiments, the sections were stained with a rat anti-PECAM-1 Alexa Fluor 488 antibody (clone 390, BioLegend) together with a rat anti-Ly6G antibody (BD Pharmingen) detected with a goat anti-rat Alexa Fluor 555 antibody (Invitrogen). DAPI was used for nuclear staining. Sections were imaged by confocal microscopy (Leica System SP5, 40x, 1.25 NA oil objective). The number of neutrophils was evaluated using Volocity software.

**Analysis of neutrophil extravasation**

TNF-α (R&D Systems, 500 ng/mouse) was applied to the scrotum of WT and Mst1−/− mice. After 2 h the cremaster muscle was dissected and fixed with 4% PFA for 1 h, permeabilized and blocked for 2 h in 0.5% Triton X-100/2% ovalbumin/PBS, incubated with rat anti-laminin α5 antibody 4G6 (Sorokin et al., 1997), rabbit anti-ESAM1 antibody (Wegmann et al., 2006) and goat anti-MRP14 antibody (S100A9, R&D Systems) overnight in 2% ovalbumin/PBS at RT. After labeling with secondary antibodies (donkey anti-rat Alexa Fluor 488, donkey anti-goat Alexa Fluor 568, donkey anti-rabbit Alexa Fluor 647, Invitrogen) in 1% ovalbumin/PBS for 5 h at RT, the tissue was embedded on glass slides in Dako Fluorescence Mounting Medium. Images were acquired using a confocal microscope (Zeiss LSM 780, LSM 510) and analyzed with Imaris software.

**Transwell assay**

HBSS buffer, 10 ng/ml or 100 ng/ml CXCL1 were used as chemoattractant in the transwell system (5 µm pore size). Isolated bone marrow neutrophils (EasySep™ mouse neutrophil enrichment kit; STEMCELL TECHNOLOGIES) were applied and allowed to migrate for 45 min at 37°C. Numbers of transmigrated neutrophils were evaluated using rat anti-Ly6G antibody (1A8, BioLegend), Flow-Count™ Fluorospheres and flow cytometry. In a second set of experiments, transwells (3 µm pore size) were additionally coated with laminin 1 (Life Technologies, 15 µg/ml) or 2% BSA (GE healthcare) as a control at 4 °C overnight. Laminin was additionally coated with PECAM-1 (R&D Systems, 2 µg/ml) and ICAM-1 (R&D Systems, 8 µg/ml) for 2 h at 37 °C. Using HBSS buffer alone (control) or HBSS buffer with 1 ng/ml CXCL1 as chemoattractant, isolated
bone-marrow neutrophils (2x10^5 cells/well) were allowed to migrate for 3 h at 37 °C (Wang et al., 2005). Numbers of transmigrated neutrophils were evaluated using rat anti-Ly6G antibody, Flow-Count™ Fluorospheres and flow cytometry. In a third set of experiments, murine endothelial 1G11 cells (generously provided by Annunciata Vecchi, Humanitas Research Hospital, Milan, Italy) were seeded on transwell inserts (5 µm pore size). Either HBSS buffer alone or HBSS buffer containing 100 ng/ml CXCL1 was added to the lower compartments. After 30 minutes of equilibration, isolated bone marrow neutrophils (2x10^5 cells/well) were allowed to migrate for 1 h at 37 °C. Numbers of transmigrated cells were evaluated using rat anti-Ly6G antibody and Flow-Count™ Fluorospheres with flow cytometry.

**Mobilization of VLA-3, VLA-6, NE, MST1 and Rab27a in mouse neutrophils**

Mobilization of neutrophil elastase (NE), α3 (VLA-3, CD49c) and α6 (VLA-3, CD49f) on PECAM-1, ICAM-1 and CXCL1 coated wells was performed as previously described (Wang et al., 2005). Briefly, slides were coated with either 2% BSA (control, GE healthcare) or PECAM-1 (2 µg/ml, R&D Systems), ICAM-1 (8µg/ml, R&D Systems) and CXCL1 (10 µg/ml, Peprotech) overnight at 4 °C. Isolated bone marrow neutrophils from WT and Mst1−/− mice were incubated on coated slides for 30 min at 37 °C. Cells were fixed with 4% PFA, blocked and permeabilized with PBS/ 0.1% Triton X-100/ 2% BSA and stained with a mouse anti-VLA-3 antibody (42/CD49c, BD), rat anti-VLA-6 antibody (GoH3, BioLegend), rabbit anti-NE antibody (polyclonal, Abcam), sheep anti-Rab27a antibody (R&D) and a rabbit anti-MST1 antibody (polyclonal, CellSignaling). Primary antibodies were detected using goat anti-mouse Alexa Fluor® 488, goat anti-rabbit Alexa Fluor® 546, donkey anti-sheep Alexa Fluor® 488 and goat anti-rat Alexa Fluor® 647 (Molecular Probes/ Invitrogen), respectively. Cells were embedded in PermaFluor (Thermo Scientific) and imaged by confocal microscopy (Leica System SP5, 63x, 1.4 NA oil objective). To investigate the translocation of VLA-3, VLA-6, NE, MST1 and Rab27a, fluorescence intensity profiles were obtained along a line through the cell as exemplified in **Supplementary Fig.3a**.
**In vivo NE activity assay**

NE680FAST (4 nmols per mouse, PerkinElmer) was injected i.v. TNF-α (rmTNF-α, R&D Systems, 500 ng/mouse) was applied to the scrotum of WT and Mst1−/− mice 1 h later. 2 h after TNF-α injection, the cremaster muscle was dissected and fixed with 4% PFA, permeabilized and blocked with 0.5% Triton X-100/2% ovalbumin/PBS and stained with rat anti-PECAM-1 antibody Alexa Fluor 488 (MEC13.3, BioLegend) or rabbit anti-MRP14 antibody (gift of Thomas Vogl, University Münster, Germany) and detected with a goat anti-rabbit Alexa Fluor® 546 antibody (Invitrogen). Tissue was embedded on glass slides in PermaFluor (Thermo Scientific) and imaged by confocal microscopy (Leica System SP5, 40x, 1.4 NA oil objective).

**Statistical analyses**

All data were analyzed and plotted using Graph Pad Prism 6 Software (GraphPad Software Inc., San Diego, USA). For pairwise comparison of experimental groups a paired t-test, unpaired t-test or Mann-Whitney test was performed. For multiple comparisons, a two way analysis of variance (ANOVA) was used with either Sidak’s multiple comparisons test or Tukey’s multiple comparisons test (comparison of all experimental groups against each other). A p-value < 0.05 was considered as statistically significant.
Author contributions
A.R.M.K., M.P., I.R. designed, performed and analyzed experiments, interpreted data and wrote the manuscript; K.S., U.B., G.G. and C.N performed and analyzed experiments; B.W., R.I., J.R.W., A.M. analyzed experiments; D.S.L., S.D. provided reagents critical for the project; M.M., C.K., D.V., R.H. contributed to the design of the experiments and the interpretation of the data; M.S. designed experiments, interpreted data and wrote the manuscript.

(A) Immunostaining of TNF-α stimulated cremaster muscle whole mounts from WT and *Mst1*^-/-^ mice for laminin α5 (white, BM), ESAM1 (red, endothelial junctions) and MRP14 (green, neutrophils) (n=3). Scale bar: 20 μm. (B) Illustration of a vessel cross section demonstrating the classification of transmigrating neutrophils respective to their position. Position I – neutrophils in intimate contact to the endothelium; Position II – neutrophils between the endothelium and the BM; Position III – fully transmigrated neutrophils. (C) Distribution pattern of transmigrating neutrophils respective to their positions (Pos. I-III) in WT and *Mst1*^-/-^ mice (n=3 mice, scatter blot with mean of ≥25 analyzed vessels per group, *** p < 0.001, 2way ANOVA, Sidak’s multiple comparisons test). (D-F) Neutrophil transmigration in a transwell assay (D) with or without CXCL1 stimulation through BSA (control), laminin-1 (LN-1) and LN-1, PECAM-1 (P) and ICAM-1 (I) coated filters (n= 3 mice, mean ± SEM, *** p < 0.001, ** p < 0.01, 2way ANOVA, Sidak’s multiple comparisons test), (E) with or without CXCL1 stimulation through an endothelial monolayer of 1G11 cells (n= 3 mice, mean ± SEM, *** p < 0.001, 2way ANOVA, Sidak’s multiple comparisons test), (F) to HBSS, 10ng ml^-1^ and 100ng ml^-1^ CXCL1 (n= 3 mice, mean ± SEM., 2way ANOVA, Sidak’s multiple comparisons test).
Figure 5  MST1 is required for the mobilization of VLA-3, VLA-6 and NE to the plasma membrane. Immunostaining of representative WT and Mst1−/− neutrophil on BSA or PECAM-1/ ICAM-1/ CXCL1 coated wells for (A) VLA-3, (D) VLA-6 and (G) NE. Scale bar: 5 µm. Fluorescence intensity profiles along a line through the cell for (B) VLA-3, (E) VLA-6 and (H) NE of a representative WT (black line) and Mst1−/− neutrophil (grey line) seeded on PECAM-1/ ICAM-1/ CXCL1 coated wells. Quantification of ring formation of (C) VLA-3, (F) VLA-6 and (I) NE (n= 3 mice, mean ± SEM of >50 analyzed neutrophils, *** p < 0.001, ** p < 0.01, 2way ANOVA, Sidak’s multiple comparisons test or Tukey’s multiple comparisons test). (J) NE activity (white) within venules in unstimulated and TNF-α stimulated cremaster muscle whole mounts from WT and Mst1<sup>−/−</sup> mice imaged by confocal microscopy. Venules were visualized using a rat anti-mouse PECAM-1 antibody (red) (n=3 per group). Scale bar: 50 µm.
Figure 6  Rab27a dependent vesicle transport to the plasma membrane is defective in Mst1−/− mice  Immunostaining of WT and Mst1−/− neutrophils seeded on BSA or PECAM-1/ICAM-1/CXCL1 coated wells for (A) Rab27a and (D) Rab27a (green) and MST1 (red). Scale bar: 5 µm. Fluorescence intensity profiles assessed along a line through the cell for (B) Rab27a of representative WT (black line) and Mst1−/− neutrophil (grey line) seeded on PECAM-1/ICAM-1/CXCL1 coated wells and (E) for MST1 of representative WT neutrophil seeded on BSA (grey line) or PECAM-1/ICAM-1/CXCL1 (black line) coated wells. Quantification of ring like expression of (C) Rab27a (n= 3 mice, mean ± SEM of >50 analyzed neutrophils, *** p < 0.001, unpaired t-test) and (F) MST1 in response to BSA or PECAM-1/ICAM-1/CXCL1 stimulation (n=3 mice, mean ± SEM of >50 analyzed neutrophils, *** p < 0.001, 2way ANOVA, Sidak’s multiple comparisons test).
Supplemental Figure 1  Adhesion properties of WT and Mst1<sup>−/−</sup> neutrophils. (A) MST2 protein levels of EGF-stimulated A431 cells, used as positive control, and of WT and Mst1<sup>−/−</sup> neutrophils. GAPDH served as loading control (n=3). (B) Rolling flux fraction and (C) cumulative distribution of neutrophil rolling velocity in cremaster muscle venules of WT and Mst1<sup>−/−</sup> mice 2 h after i.s. injection of TNF-α (n ≤ 5, mean ± SEM, n.s., unpaired t-test). (D) FACS analysis of WT and Mst1<sup>−/−</sup> neutrophils for surface expression of LFA-1, Mac-1, CXCR2, CD44, PSGL-1, CD62L and corresponding isotype controls. The mean fluorescent intensity (MFI) was evaluated relative to the isotype control on Ly6G<sup>+</sup> cells (neutrophils) (n= 3 mice, mean ± SEM, n.s., unpaired t-test). (E,F) FACS analysis of ICAM-1 binding to (E) WT or (F) Mst1<sup>−/−</sup> neutrophils with or without CXCL1 stimulation (n=5 * p < 0.05, ** p<0.01 paired t-test).
Supplemental Figure 2  Chemotactic migration of WT and Mst1−/− neutrophils. (A,B) Chemotactic migration of WT and Mst1−/− neutrophils seeded in 3D collagen gels towards a gradient of (A) fMLP or (B) CXCL1 for 30 min. Neutrophils were tracked using Fiji software (Schindelin et al., 2012). Accumulated distance, velocity and directionality of cells were evaluated (n= 3, scatter blots with mean, n.s., unpaired t-test).
**Supplemental Figure 3**  
VLA-3, VLA-6 and NE – protein levels, distribution and NE activity.  
Fluorescence intensity profiles along a line cut through the center of the cell as exemplified in (A) for (B) VLA-3, (C) VLA-6 and (D) NE of a representative WT (black line) and Mst1−/− neutrophil (grey line) seeded on BSA coated wells. Scale bar: 5 µm. (E) Total protein levels of VLA-3, VLA-6 and NE from neutrophils of WT and Mst1−/− mice. GAPDH served as loading control (n=3 mice). (F) Immunostaining of MRP14 (green) in TNF-α stimulated cremaster muscle whole mounts from WT and Mst1−/− mice (n=3 per group). Scale bar: 50 µm.
**Supplemental Figure 4** Protein levels and distribution under unstimulated conditions of Rab27a. (A) Fluorescence intensity profile along a line cut through the center of the cell for Rab27a of a representative WT (black line) and Mst1⁻/⁻ neutrophil (grey line) seeded on BSA coated wells. (B) Total protein levels of Rab27a from neutrophils of WT and Mst1⁻/⁻ mice. GAPDH served as loading control (n=3 mice).

**Supplemental Movie 1** LFA-1 clustering in WT and Mst1⁻/⁻ neutrophils. **Whole Blood from** (A) **WT and (B) Mst1⁻/⁻** mice was incubated with a non-blocking LFA-1 antibody AND PERFUSED THROUGH FLOW CHAMBERS COATED WITH E-SELECTIN, ICAM-1 AND CXCL1. Using confocal microscopy, interacting cells were recorded under flow conditions. Images were recorded for 195 s (one stack every 13 s). The movies were generated and converted using Fiji software.

**Supplemental Movie 2** Intravital multi photon laser scanning microscopy of transmigrating neutrophils. Extravasation of neutrophils (green) was recorded from postcapillary venules (red) in a TNF-α stimulated mouse cremaster muscle of (A) Lyz2⁻/⁻ and (B) Mst1⁻/⁻ x Lyz2⁻/⁻ mice. Z-stacks of postcapillary venules were obtained every 30 seconds over a time period of 240 min. Sequences of z-stacks were processed and converted using Imaris 7 and Fiji software.

**Supplemental Movie 3** Intravital multi photon laser scanning microscopy of laser injury. Four hours after intrascrotal injection of TNF-α in (A) Lyz2⁻/⁻ and (B) Mst1⁻/⁻ x Lyz2⁻/⁻ mice, a laser injury was induced near postcapillary cremaster muscle venules (red). Swarming of neutrophils (green) was then recorded to the sites of laser injury. Z-stacks of postcapillary venules (red) were obtained every 30 seconds over a time period of 30 min. Sequences of z-stacks were processed and converted using Imaris 7 and Fiji software.

I hereby declare, that the submitted thesis entitled

**MST1 kinase is critical for neutrophil transmigration through the vascular basement membrane**

is my own work. I have only used the sources indicated and have not made unauthorised use of services of a third party. Where the work of others has been quoted or reproduced, the source is always given.

I further declare that the submitted thesis or parts thereof have not been presented as part of an examination degree to any other university.
