Tag der Abgabe: 14.03.2017

Tag der mündlichen Prüfung: 18.05.2017

Eidesstattliche Versicherung und Erklärung:

Hiermit versichere ich an Eides statt, dass die vorliegende Dissertation von mir selbstständig und ohne unerlaubte Hilfe angefertigt wurde.

Des Weiteren erkläre ich, dass ich nicht anderweitig ohne Erfolg versucht habe, eine Dissertation einzureichen oder mich der Doktorprüfung zu unterziehen. Die vorliegende Dissertation liegt weder ganz, noch in wesentlichen Teilen einer anderen Prüfungskommission vor.

Yang Wang

Statutory Declaration:

I declare that I have authored this thesis independently, that I have not used other than the declared sources/resources. I declare that I have not submitted a dissertation without success and not passed the oral examination. The current dissertation (neither the entire dissertation nor parts) has not been presented to another examination board.

Abbreviations

5-Aminolevulinic acid	ALA
6His/His tag	Six histindine tag
Ap^R	Ampicillin resistance
ATP	Adenosine triphosphate
BCIP	5-bromo-4-chloro-3-indolyl-phosphate
c-di-AMP	3′,5′-Cyclic diadenylic acid
cDNA	Complementary DNA
Cip	CipA or CipB protein
cryo-EM	Cryo-electron microscopy (cryo-EM)/electron cryomicroscopy
DM	n-dodecyl b-D-maltoside
DMPC	1,2-dimyristoyl-*sn*-glycero-3-phosphocholine
DPPC	1,2-Dipalmitoyl-*sn*-glycero-3-phosphocholine
DUF XXX (e.g DUF4118)	Domain of unknown function
EAL	Putative diguanylate phosphodiesterase
EBP	Enhancer binding protein
Em^R	Erythromycin resistance
E-value	Expect value
FM	Fluorescence microscopy
GAF	cGMP-specific phosphodiesterases, adenylyl cyclases and FhlA
GFP	Green fluorescent protein
HAMP	(Histidine kinases, Adenylyl cyclases, Methyl binding proteins, Phosphatases) domain
HATPase_C	Histidine kinase-like ATPase, C-terminal domain
HDc	Metal dependent phosphohydrolases with conserved 'HD' motif
HGT	Horizontal gene transfer
HisKA	His Kinase A (phospho-acceptor) domain
HK	Histidine kinase
HK^{K+}	Histidine kinase perceives K^+ signal
HMM	Hidden Markov Model
HPLC	High-performance liquid chromatography
HPT	Histidine phosphotransferase
HTH	Helix-turn-helix

kDa	Kilodalton
Km^R	Kanamycin resistance
LDAO	lauryldimethylamine oxide
MSA	Multiple sequence alignment
MSP	Membrane scaffold protein
NAD(P)+	β-Nicotinamide adenine dinucleotide (2′-phosphate)
NADB_Rossmann	Rossmann-fold $NAD(P)^+$-binding
NMR	Nuclear magnetic resonance
NTB	Nitro blue tetrazolium
Nucleotidyl_cyc_IIIyl_cyc_III	Class III nucleotidyl cyclases
OD600	Optical density measured at a wavelength of 600 nm
ORF	Open reading frame
PAC	Motif C-terminal to PAS motifs (likely to contribute to PAS structural domain)
PAS	Per Arnt Sim
PCI(s)	Protein crystalline inclusion(s)
PCM	Phase contrast microscopy
PCR	Polymerase chain reaction
POPC	1-palmitoyl-2-oleoyl-*sn*-glycero-3-phosphocholine
PTS_EIIA_2	Phosphoenolpyruvate-dependent sugar phosphotransferase system, EIIA 2
qPCR	Real-Time PCR/Quantitative PCR
qRT-PCR	Quantitative reverse transcription polymerase chain reaction
REC	Signal receiver domain
RNAP	RNA polymerase
RR	Response regulator
RR^{K+}	Response regulator involves in K^+ signal responding
SD sequence	Shine-Dalgarno sequence
SDS-PAGE	Sodium dodecyl sulfate-polyacrylamide gel electrophoresis
SK	Sensor kinase
Sm^R	Streptomycin resistance
TCS	Two component system
Tet^R	Tetracycline resistance
URP	UniProt reference proteomes
Usp	Universal stress protein
v/v	Volume per volume
w/v	Weight per volume

Nomenclature

●Promoter of an operon: "$P_{\text{operon name}}$", for example promoter of the *kdp* operon P_{kdp}.

●Deletion of gene *A*, "Δ*A"*.

●DNA element insertion between gene *A* and gene *B*: "*A*::inserted DNA element::*B*".

●Gene *A*/promoter *A* replaced by a new DNA element, "Δ A/P_A::new DNA element".

● Gene/protein fusion between *A* and *B* with *A* located at the N or 5' terminus, "*gene A-gene B*"/"protein A-protein B". No linker was used for the fusion, for example *cipA-gfp* or CipA-GFP.

●Several genes/proteins separately fused to a same gene *X*/protein X, with *X* located at the N or 5' terminus:" gene *X*-(*gene A*,*gene B*,*gene C*)" or "protein X-(protein A, protein B, protein C)", for example *cipA*-(*vioA*,*vioB*) or CipA-(VioA,VioB).

●Amino acids are denoted with three letter codes or one letter code.

Contribution

1. Section 3.1.5, the related Figure 14 and Table 5 were contibuted by the collabrators: Prof. Dr. Dirk Metzler, Dr. Noémie Becker and Dr. Sonja Grath, Evolutionary Biology, LMU Munich.
2. The plasmid pNBU1-PKdp-NanoLuc (in Table 2 of section 2.2.4) used for the construction of *B. fragilis* Wlu reporter stain was generated by Dr. Mark Mimee from the group Prof. Dr. Timothy Lu, MIT.
3. Mass spectrometry of KdpD 38-380 (in Figure 22B) was performed by Dr. Markus Hartl, Plant Science of LMU Munich
4. Expression of CipA-GFP and CipB-GFP in insect cells (Figure 25) and serial crystallography of PCIs were performed by the collabrator Dr. Lars Redecke, Universitäten Lübeck und Hamburg.

1 Introduction

1.1 Bacterial signal transduction and two component system (TCS)

Bacterial cells face various environmental changes on nutrients, toxicity, temperature, light, osmolality, pH, and in some occasions they need intraspecies or interspecies cell to cell communications (Galperin 2004, Waters and Bassler 2005). These activities depend on different signal transduction mechanisms. The most prevalent signal transduction pathways are one-component system and two-component system (TCS) (Ulrich, Koonin et al. 2005). The TCS is typically composed of a sensor histidine kinase (HK) and a cognate response regulator (RR) (Figure 1).

HK has a dimerization and phosphoacceptor domain (HisKA domain) as well as an ATP binding HATPase_c domain, as the output region. The output region of the HK is bifunctional that can carry out both autophosphorylation and dephosphorylation of the conserved histidine residue in the HiskA domain (Kennelly 2002, Klumpp and Krieglstein 2002). Besides, HK generally has a signal input region composed of various protein domains like transmembrane helices, periplasmic domains or cytoplasmic domains including GAF, PAS, HAMP *etc* (Mascher, Helmann et al. 2006). The signal input domain perceives extra- and/or intracellular signals and hence regulates the kinase and phosphatase activities of the output region (Schramke, Wang et al. 2016).

RR of TCS typically has a signal receiver domain (REC domain) which could be phosphorylated by the HK and an effector domain which may be a DNA-binding domain (helix-turn-helix domain, HTH) or an enzymatic domain. In a few case, the REC domain protein can be a stand-alone protein which participates in protein-protein interactions, for example the CheY protein of bacteria chemotaxis system (Galperin 2006). Typically, a phosphoryl group is transferred from ATP to the HisKA domain of HK by the catalysis of HATPase_c domain and subsequently to the conserved aspartate in the REC domain of RR. Phosphorylation may

cause the dimerization of RR and activates/enhances its DNA-binding capability or modulate the enzyme activity of the effector domain (Galperin 2006, Capra and Laub 2012). When the output domain of the RR is the HTH domain, the response activity of RR is generally a transcriptional initiation of one or serval operons via interacting with the sigma factor and the RNA polymerases (RNAP) (Figure 1).

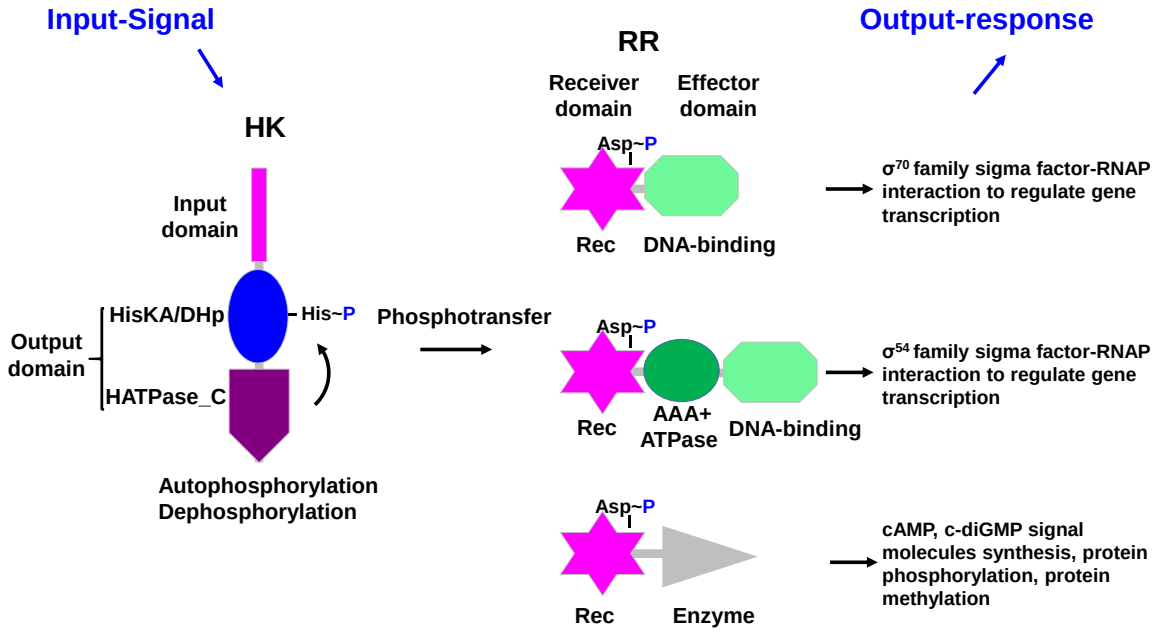

Figure 1: Schematic of the typical mechanism of TCS. The core elements of bacterial TCS comprise HK and RR. HK perceives extra- and/or intracellular signals and processes them into phosphorylation and dephosphorylation reactions to the REC domain of the RR. Phosphorylated RR may exhibit altered DNA-binding affinities, enzymatic activities or protein interaction capabilities to regulate the response of the cells.

1.2 K^+ transport and the K^+ responding TCS -- KdpD/KdpE

K^+ is the most abundant cation in cells and participates in turgor regulation, metabolism, virulence and intercellular communication (Epstein 2003, Su, Gong et al. 2009, Arlehamn, Pétrilli et al. 2010, Xue, You et al. 2011, Prindle, Liu et al. 2015). K^+ transporters with low and high affinities, different uptake kinetics and expression patterns have been identified. In *E. coli,* the constitutively expressed Trk systems, which include TrkA-TrkH-TrkE and TrkA-TrkG-TrkE

complexes (Dosch, Helmer et al. 1991, Schlosser, Meldorf et al. 1995) and Kup (Schleyer and Bakker 1993, Trchounian and Kobayashi 1999), represent low-affinity K^+ transport systems, while KdpFABC operates as a high-affinity transporter (Figure 2). Expression of the *kdpFABC* operon is induced in response to K^+ limitation (Walderhaug, Polarek et al. 1992, Altendorf, Voelkner et al. 1994, Heermann, Weber et al. 2009, Heermann and Jung 2010, Freeman, Dorus et al. 2013, Laermann, Ćudić et al. 2013) under the control of the histidine kinase/response regulator (HK/RR) system KdpD/KdpE.

1.3 Domain composition of the KdpD proteins

1.3.1 "Full-length" KdpD with kinase function

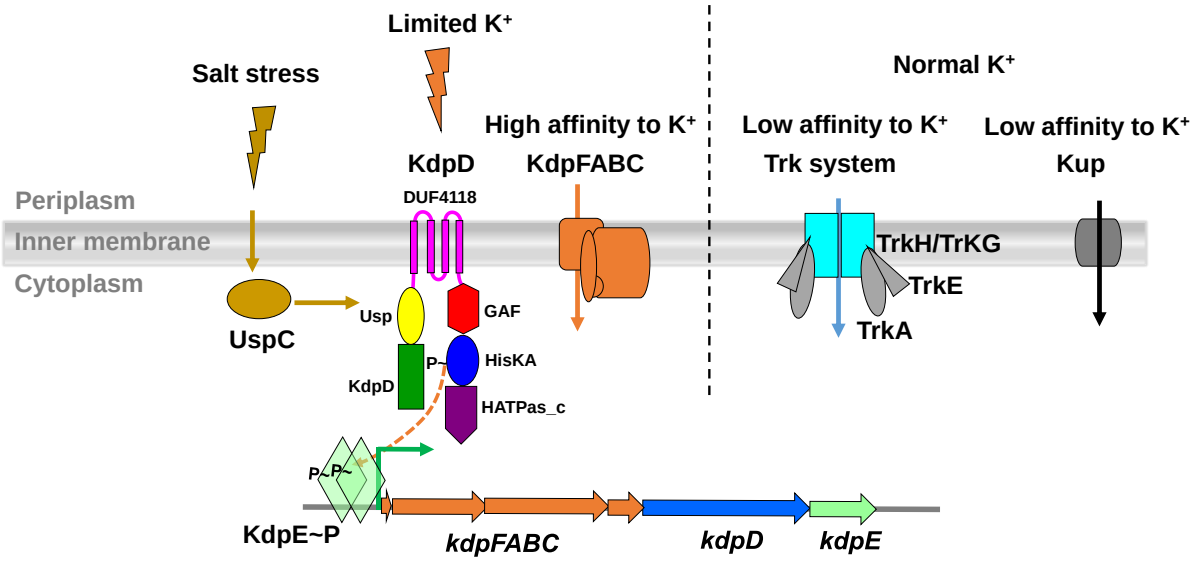

Figure 2: Components of the Kdp system of *E. coli*. KdpFABC is a high-affinity K^+ transporter. Its expression is regulated by the HK/RR--KdpD/KdpE system in response to K^+ availability and the cell's demand for K^+. KdpD consists of the following domains: KdpD, Usp, DUF4118, GAF, HisKA and HATPase_c. K^+ limitation causes autophosphorylation of KdpD and transfer of the phosphoryl group to KdpE. Phosphoryated KdpE dimerizes and activates the $P_{kdpFABC}$ promoter to promote the production of KdpFABC transport, which in turn relieve the stress of K^+ limitation.

As discussed above KdpD protein was firstly known from *E. coli*, as HK. Comparing to the other bacterial HKs, the stimulus-perceiving region of *E. coli* histidine kinase KdpD is rather

unique (Jung and Altendorf 2002, Mascher, Helmann et al. 2006). It is made up of four domains: the cytosolic N-terminal KdpD (PF02702) and Usp (PF00582) domains, the four-helix transmembrane domain, DUF4118 (PF13493), and a GAF (PF01590) domain (also found in c**G**MP-specific phosphodiesterases, **a**denylyl cyclases and **F**hlA). It is connected to the C-terminal signal transmitter module [comprising HisKA (PF00512) and HATPase_c (PF02518) domains), which contains the autophosphorylation site (Figure 2). The N-terminal region comprising KdpD and Usp domain is localized in the cytoplasm and is important for stabilizing the KdpE-DNA complex and integrating the salt stress signal via interaction with UspC, which acts as a scaffold protein (Figure 2) (Heermann, Altendorf et al. 2003, Heermann, Lippert et al. 2009). The transmembrane domain DUF4118 was found to be important for K^+ and osmostress sensing, and its conformation determines the spatial relationship between the N- and C-terminal cytoplasmic domains of KdpD (Heermann, Fohrmann et al. 2003, Zimmann, Steinbrügge et al. 2007, Heermann and Jung 2010). NMR analysis indicates that the DUF4118 domain forms a tightly packed four-helix bundle (Maslennikov, Klammt et al. 2010).

1.3.2 "Truncated" KdpD without kinase function

In several bacterial species, e.g. *Anabaena* sp. strain L31, *Synechocystis* sp. strain PCC 6803 and *Deinococcus radiodurans*, the cytosolic N-terminal domain of KdpD is encoded as an independent protein. It is often described as "truncated KdpD", because comparing to the *E. coli* KdpD, these KdpD proteins have much shorter length and the transmembrane domain and the essential kinase module (HiskA and HATPase_c domain) are "missing" (Ballal and Apte 2005, Ballal, Bramkamp et al. 2005, Ballal, Basu et al. 2007, Nanatani, Shijuku et al. 2015). That is to say, in these bacteria, the KdpD domain-containing proteins (will be called as KdpD proteins) are literally not histidine kinases.

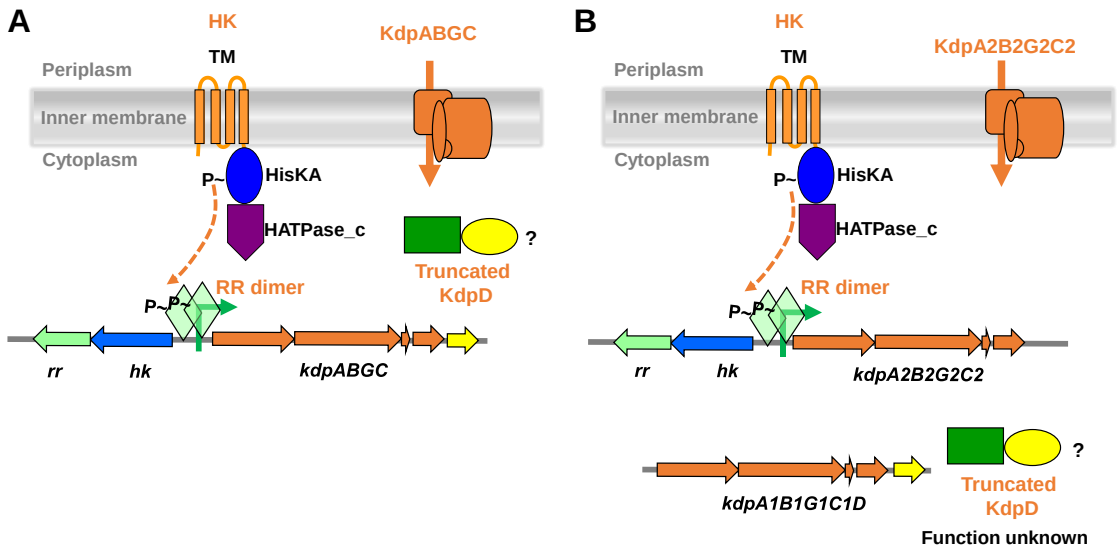

Figure 3: Models of Kdp system in *Cyanobacteria*. (A) Kdp system of *Synechocystis* sp. strain PCC 6803. In response to K^+ concentration, the expression of high-affinity K^+ transporter KdpABGC is regulated by the HK^{K+}/RR^{K+} encoded at its upstream. Deletion of *kdpD* genes does not affect the response of *kdp* operon to K^+. **(B)** Kdp system of *Anabaena* sp. strain L-31. *Anabaena* sp. strain L-31 has two *kdp* operons. The *kdpD* ORF is included in one the *kdp* operons whose expression is not efficiently induced by low K^+ [Modified based on (Ballal and Apte 2005)]. "Truncated KdpD" in both *Synechocystis* sp. strain PCC 6803 and *Anabaena* sp. strain L-31 consist of two domains--KdpD and Usp. The function of "truncated KdpD" in these cyanobacterial species is unknown.

1.4 Alternative HK/RR involved in K^+ response

It is apparent that the "truncated KdpD" described above cannot functionalize as HK without the fundamental output domains of HiskA and HATPase_c. However, genes for a HK that lacks KdpD and Usp domains and a RR that is homologous to KdpE were found in the vicinity of the gene for the "truncated KdpD" in *Anabaena* sp. strain L31 and *Synechocystis* sp. strain PCC 6803 (Figure 3). Deletion of the *kdpD* genes encoding the "truncated KdpD" in *D. radiodurans* and *Synechocystis* sp. strain PCC 6803 does not affect the *kdp* operons expression (Ballal, Basu et al. 2007, Nanatani, Shijuku et al. 2015). Conversely, the HK/RR encoded in genomic neighborhood of *kdpD* have been shown essential for K^+ sensing (Ballal and Apte 2008, Nanatani, Shijuku et al. 2015). For simplicity, the alternative HK/RR, which have been proved or predicted to involve in K^+ response, will be called alternative HK^{K+}/RR^{K+}.

In *E. coli*, various cyanobacterial species and in *S. aureus*, the RR that regulates expression of *kdpFABC* (or *kdpABGC*), functions together with the σ^{70} family sigma factor for transcriptional initiation. In contrast, it was suggested that the *kdp* promoter in *Desulfovibrio vulgaris* Hildenborough can be recognized by σ^{54}-dependent transcriptional activators (Rajeev, Luning et al. 2011).

1.5 *Bacteroides fragilis*

B. fragilis attracts lots of attentions and concerns (Wexler 2007). The main habitat of this species is the mammal gut, which is an anaerobic and K^+ rich environment. While Kdp system, as described above, is commonly equipped to the species to cope with K^+ limitation. From this respect, there seems no point for this bacterium to preserve the Kdp system. However, as will be discussed in the results section, many proteomes of the *Bacteroidetes/Chlorobi* group species, including *B. fragilis* were found to contain both KdpD and KdpA proteins. Until now, there is no report on the Kdp system in *Bacteroides fragilis*.

1.6 Structure of KdpD protein

As a multidomain protein, the tertiary structure of KdpD has not been elucidated. But the structures of DUF4118 and (KdpD 397-502) and GAF domains (KdpD 515-646[3920]) of *E. coli* KdpD have been resolved by NMR and crystallography, respectively (PBD IDs: 2KSF and 4QPR) (Maslennikov, Klammt et al. 2010). Moreover, the KdpD domain structure (KdpD 19-243) of *Pseudomonas syringae* pv. *tomato* str. DC3000 HK KdpD was also published (PDB ID: 2R8R). The DUF4118 domain has four-helix bundle, the helices were sperated by very short loops (Figure 4A). The GAF domain has four α-helices and four β-sheet strands. Especially the last α-helix is quite long and comprises 35 amino acids (Figure 4B). The KdpD domain is composed of seven α-helices and six β-sheet strands. They were crystallized with binding SO_4^{2-} ion (Figure 4C) (Berman, Westbrook et al. 2000).

The architecture of the HisKA and HATPase_c domain are better research. For example, these two domains contained in *E. coli* kinases QseC, EnvZ, CpxA have been analysed via crystallography.

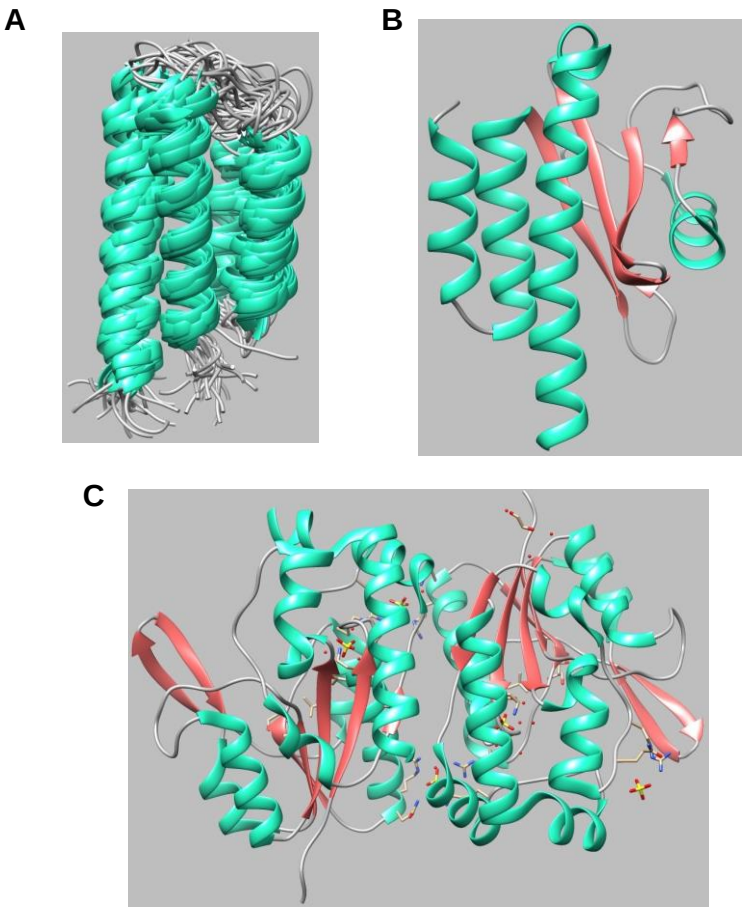

Figure 4: **Three dimensional structure of DUF4118, GAF and KdpD domains. (A)** NMR structure of the transmembrane domain DUF4118 of *E. coli* KdpD protein. **(B)** Crystal structure of the GAF domain of *E. coli* KdpD protein. **(C)** Crystal structure of the KdpD domain dimer (with binding $SO4^{2-}$ ion) of *Pseudomonas syringae* KdpD protein. These three figures are snapshots of the corresponding three dimensional structures downloaded from PDB database (Berman, Westbrook et al. 2000).

1.7 *In vivo* protein organization and protein crystallization

As described in section 1.6, even though there are different methods to determine the protein structures, crystallography is still the most successful strategy to study protein structures. In addition to the common crystallization setups, *in vivo* protein crystallization is a clever trick to

get diffractive crystals for solving protein structures (Koopmann, Cupelli et al. 2012). Protein crystals formed *in vivo* may be considered as protein complexes or protein crystalline inclusions (PCIs), which assemble automatically in the cytoplasm.

Proteins can be organized *in vivo* into various structures--compartments such as carboxysomes (Yeates, Kerfeld et al. 2008, Kerfeld and Melnicki 2016) and gas vesicles (Pfeifer 2012), or protein inclusions like the parasporal crystalline inclusion (Bt crystals) (Agaisse and Lereclus 1995, Schnepf, Crickmore et al. 1998) and refractile body (R body) (Pond, Gibson et al. 1989, Polka and Silver 2016). Some special proteins can automatically assemble into diffractive PCIs (*in vivo* protein crystals) in cells. For example, two *in vivo* protein crystals formed respectively in insect cells and in *Bacillus thuringiensis* have been successfully used for protein structure determinations with serial femtosecond X-ray free-electron lasers (Boutet, Lomb et al. 2012, Sawaya, Cascio et al. 2014).

1.8 CipA and CipB and their application potentials as scaffolds for *in vivo* protein crystallization

CipA and CipB are small proteins of 104 and 100 amino acids respectively, which are found in the entomopathogenic bacterium *Photorhabdus luminescens* (Figure 5A) (Bintrim and Ensign 1998, Bowen and Ensign 2001). CipA and CipB PCIs appear refractile when viewed by phase-contrast microscopy, and exhibit polyhedral configurations in the scanning or transmission electron microscope (Bintrim and Ensign 1998, Bowen and Ensign 2001). The mechanism underlying their organization into PCIs is unknown. The hydrophobicity is speculated to be the primary driving force, because both proteins contain high proportions of hydrophobic amino acids (CipA and CipB comprise, respectively, 49.0 % and 51.0% hydrophobic amino acids, Figure 5B).

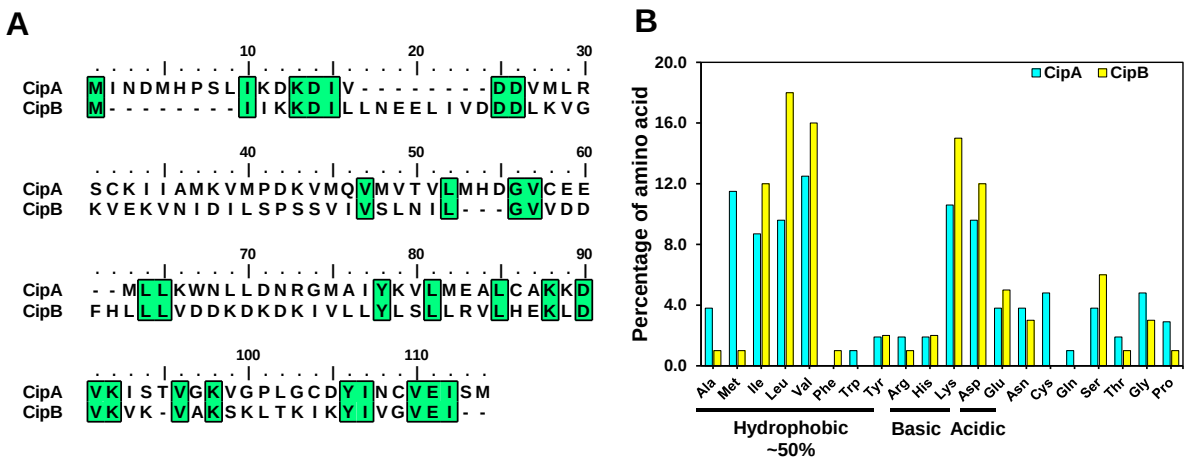

Figure 5: CipA and CipB protein sequences analysis. (A) Sequence comparison of CipA and CipB (indentical amino acids are highlighted in green). **(B)** Relative abundance of individual amino acids in CipA and CipB. (Hydrophobic, acidic and basic amino acids are underlined).

1.8.1 CipA and CipB as scaffolds to boost protein *in vivo* crystallization

As shown above, there are two *in vivo* grown crystals, which have been used for structural analysis. They are actually composed of natural proteins without any artificial design (Boutet, Lomb et al. 2012, Sawaya, Cascio et al. 2014). *In vivo* protein crystallization is particularly mystifying and the relevant mechanism remains unexplored.

Considering the small sizes of CipA and CipB and their PCIs forming capabilities, they may be potentially used as protein tags or scaffolds to bring other proteins into diffractive protein crystals *in vivo*, so that the method of *in vivo* crystallization could be extended to more proteins.

1.8.2 CipA and CipB as scaffolds to organize enzymes into PCIs for biotechnological applications

Based on the principles of natural protein organization, various types of synthetic protein scaffolds have been developed to artificially organize proteins with a view to promoting *in vivo* or *in vitro* biotechnological processes (Whitaker and Dueber 2011, Lee, DeLoache et al. 2012) or mimicking the function of organelles (Kim and Tullman-Ercek 2013, Huber, Schreiber et al.

2015). For example, to fine-tune metabolic flux through mevalonate and glucaric acid biosynthetic pathways, the related enzymes have been spatially organized into supramolecules via the scaffolding of signaling protein interaction domains (Dueber, Wu et al. 2009). At subcellular scales, a lipid-containing scaffold has recently been developed that can co-organize two enzymes involved in indigo biosynthesis into lipid-bound compartments in *Escherichia coli* for the purpose of metabolic engineering (Myhrvold, Polka et al. 2016). The cohesin-dockerin scaffold has been used to display multiple enzymes on bacterial outer membrane vesicles for *in-vitro* cascade reactions (Park, Sun et al. 2014). An ethanol bioreactor was generated by incorporating the corresponding enzymes into an intracellular compartment normally devoted to 1,2-propanediol utilization in *Citrobacter freundii* (Lawrence, Frank et al. 2014). Moreover, a method for scaffold-free self-assembly of the octameric leucine dehydrogenase and dimeric formate dehydrogenase has been developed (Gao, Yang et al. 2014).

Simililarily, CipA and CipB may be developed in to protein scaffolds to bring enzymes into PCIs for biotechnological applications.

1.9 Scope of the thesis

The overall scope of the thesis is aimed to reveal the evolutionary routes and the three dimensional structure of KdpD proteins.

Evolutionary analysis of KdpD proteins is aimed to: **(i)** Systematically analyze the distribution, architecture and evolution of KdpD domain-containing proteins (“KdpD proteins”) in the three domains of life; **(ii)** Predict and prove new alternative HK^{K+}/RR^{K+} involved in *kdp* operon regulation in various bacterial species.

As shown above, there are two versions of KdpD proteins, “full-length” and “truncated KdpD proteins. The structure of the former one is aimed to be analyzed via protein crystallization or

cryo-EM in membrane lipid bilayer. “Truncated” KdpD protein is composed of KdpD and Usp domains without any transmembrane helix. Therefore, “truncated” KdpD will be purified and crystallized as soluble proteins.

CipA and CipB, as the original aspiration, will be tested as scaffolds to bring “truncated” KdpD proteins into *in vivo crystals* for the purpose of X-ray crystallography. In addition, the biotechnological applications of CipA and CipB proteins shall be evaluated.

2 Materials and Methods

2.1 Bioinformatic analyses

2.1.1 Identification and collection of proteins containing KdpD, KdpA, TrkH or DUF4118 domain

A database was created from UniProt reference proteomes 2015_10 (URP), which provides broad coverage of all three domains of life as well as high-quality annotation of protein sequences (UniProt 2015). HMMER 3.0 was utilized to construct Hidden-Markov Models (HMM) and query URP for proteins containing KdpD (PF02702), KdpA (PF03814), TrkH (PF02386) or DUF4118 (PF13493) domains with the respective cut-off values defined by Pfam 26.0 (Finn, Clements et al. 2011, Finn, Bateman et al. 2014). Proteins containing KdpD, KdpA or TrkH domains related to K^+ sensing/uptake were collected and grouped as KdpD, KdpA and TrkH proteins, respectively.

Domain architectures of entire KdpD proteins or proteins containing a DUF4118 domain were annotated with CDD v3.14 (the interface of CDD database is CD-search), using a cut-off *E*-value of 0.01 (Marchler-Bauer, Derbyshire et al. 2015). When domains were predicted to be overlapping, the one with the lowest *E*-value was adopted.

2.1.2 Phylogeny reconstruction and detection of selection pressure

Protein sequence alignments were performed with Mafft and gaps were removed with trimAl v1.2 (Capella-Gutierrez, Silla-Martinez et al. 2009). All Maximum Likelihood protein trees were constructed with PhyML 3.0 (Anisimova and Gascuel 2006, Guindon, Dufayard et al. 2010). Nucleotide sequences for the KdpD proteins were retrieved from the protein sequences using tBlast (Altschul, Gish et al. 1990) and Entrez queries. Program CodonPhyML was used to infer the phylogeny of nucleotide sequences (Gil, Zanetti et al. 2013).

Selection pressure was tested using the program CODEML from the PAML v4.8 package (Yang 2007), which uses the ratio ω of the rates of non-synonymous and synonymous mutations to test for selection on specific branches of the tree.

2.1.3 Prediction of protein structures and display phylogenetic trees

Transmembrane regions were predicted with TMHMM 2.0 (Krogh, Larsson et al. 2001) and DAS (Cserzo, Wallin et al. 1997); The three dimensional structure of the outer membrane porin KdpO was predicted with HHpred (Soding, Biegert et al. 2005). The secondary structures of CipA and CipB were predicted with PSIPRED server (Jones 1999).

All trees were displayed using iTOL v3 (Letunic and Bork 2016).

2.2 Experimental analyses

2.2.1 Common methods and chemicals

2.2.1.1 Genomic DNA and plasmid extraction

Genomic DNA was extracted with UltraClean Microbial DNA Isolation Kit of Mo Bio. Plasmid was extracted using the Hi Yield MINI Plasmid DNA Extraction Kit of Süd-Laborbedarf. Genomic DNA samples and plasmids were stored at -20 °C.

2.2.1.2 PCR reaction

PCR reactions with high fidelity (for gene deletion and vector construction) were performed with Phusion® High-Fidelity DNA Polymerase of New England Biolabs. Colony PCR reactions were performed with OneTaq® DNA Polymerase of New England Biolabs.

2.2.1.3 DNA restriction and ligation

DNA restrictions and ligations were performed with the specific restriction enzymes and T4 DNA ligase purchased from New England Biolabs following the manufacturer's instructions.

Before each ligation, dephosphorylation of 5´ and 3´ ends of restricted vectors was performed with the calf intestinal alkaline phosphatase of New England Biolabs.

2.2.1.4 DNA purification/isolation

After PCR or DNA restriction, the target DNA were separated with DNA agarose gel electrophoresis (in Tris-HCl-acetate EDTA buffer, pH 8.3). Agarose slices with desired DNA bands were dissolved for sample recovery with Hi Yield Gel/PCR DNA Fragment Extraction Kits of Süd-Laborbedarf.

2.2.1.5 DNA sequence analysis

DNA sequencing experiments were performed in the Department of Genetics of LMU Munich with the BigDye v3.1 protocol of Thermo Fisher Scientific.

2.2.1.6 Preparation of *E. coli* competent cells and transformation of DNA

E. coli competent cells were prepared with calcium chloride, following the protocol described before (Seidman, Struhl et al. 1997). Transformations of *E. coli* strains with plasmids were performed with the heat shock method (Seidman, Struhl et al. 1997). Transformations of *E. coli* strains with liner DNA were performed with electro-transformed into *E. coli* strains as described in Quick & Easy *E. coli* Gene Deletion Kit (Gene Bridges).

2.2.1.7 SDS-PAGE and gel development

Denaturing protein gel electrophoresis (SDS-PAGE) was performed as described (Laemmli 1970). Unless specified, the polyacrylamide concentration of the gels used in this thesis was set to12.5% (w/v). Gels may be either stained by Coomassie Brilliant Blue R-250 (stained with 50% (v/v) methanol, 10% (v/v) acetic acid in H_2O for two hours and destained with 5% methanol (v/v), 7.5% acetic acid (v/v) in H_2O until background disappeared) or Coomassie Brilliant Blue G-250 (in water with ~10mM of H_2SO_4) for visualization of the bands or transferred

to methanol activated PVDF membrane (300 mA for 90 min in 25mM Tris-HCl, 192 mM glycine and 20% methanol) for Western blot.

Table 1 lists the common chemicals used in this study. The other chemicals or materials not listed were purchased from Carl Roth, Fluka, Sigma-Aldrich, or Merck Millipore.

Table 1: Common materials and chemicals

Material	Manufacturer
>98% violacein (>=85%) and deoxyviolacein	Sigma-Aldrich
2-Log DNA-Ladder	New England Biolabs
5-Aminolevulinic acid hydrochloride	Sigma-Aldrich
5-Bromo-4-Chloro-3-Indoxyl Phosphate (BCIP)	AppliChem
Acetonitrile	Fluka
Acrylamide Protogel	Biozym Diagnostik
Agarose	Serva
All Restriction Nucleases	New England Biolabs
Ammonium Persulfate (APS)	National Diagnostics
Ampicillin (sodium salt)	Carl Roth
Anti-GFP Antibody	Thermo Fisher Scientific
Anti-Mouse Secondary Antibodies	Rockland Immunochemicals
Anti-Rabbit Secondary Antibodies	Rockland Immunochemicals
Bovine Serum Albumin (BSA)	AppliChem
Brain Heart Infusion	BD Bacto
Brillant Blau G250	Carl Roth
Brillant Blau R250	Carl Roth
Calf Intestinal Phosphatase (CIP)	New England Biolabs
Chloramphenicol	Sigma-Aldrich
Chloroform	Carl Roth
Congo red	Merck Millipore
DNA oligonucleotides	Sigma-Aldrich
DNase I	Sigma-Aldrich
dNTPs (deoxynucleotide triphosphates)	Invitrogen
Erythromycin	Sigma-Aldrich
Folin-Ciocalteu's phenol reagent (2N)	Merck Millipore
Glycerol	Carl Roth
Hemin Chloride	Carl Roth
Hi Yield PCR Clean-Up & Gel-Extraction Kit	Süd-Laborbedarf
Hi Yield Plasmid Mini Kit	Süd-Laborbedarf
Hybond-P protein transfer membrane	GE Healthcare
iQ SYBR Green Supermix	Bio-Rad

Material	Manufacturer
Kanamycin (sulfate)	Carl Roth
L-(+)-Arabinose	Carl Roth
N,N,N′,N′-Tetramethylethylenediamine (TEMED)	Carl Roth
Nano-Glo Luciferase Assay System	Promega
Ni-NTA agarose	Qiagen
Nitro Blue Tetrazolium (NBT)	Biomol
Nitrocellulose membrane	GE Healthcare
o-Nitrophenyl β-D-galactopyranoside (*o*NPG)	Carl Roth
Page Ruler Prestained Protein Ladder	Fermentas
Penta·His Antibody	Qiagen
Phenol/Chloroform/Isoamylalcohol (25/24/1)	Carl Roth
Phenol-Chloroform	Carl Roth
Phenylmethylsulfonyl fluoride (PMSF)	Sigma-Aldrich
Phusion DNA Polymerase	New England Biolabs
Quick & Easy *E. coli* Gene Deletion Kit	Gene Bridges
RevertAid H Minus First Strand cDNA Synthesis Kit	ThermoFisher
Ribonuclease	Carl Roth
T4-DNA ligase	New England Biolabs
Tetracycline Hydrochloride	Sigma-Aldrich
Vitamin K1	Sigma-Aldrich

2.2.2 Medium and cultivation

Strains used in this part of study are listed in Table 2. *E. coli* DH5α was used to construct all the plasmids. *E. coli* S17-1 λpir or *E. coli* ST18 (Strand, Lale et al. 2014) were used for conjugation plasmids into *B. fragilis* and *P. luminescens* strains. LB medium (10 g/L NaCl, 10 g/L Tryptone, 5 g/L yeast extract) (Bertani 1951) was used to cultivate *E. coli* strains. For cultivation of *E. coli* ST18, a *hemA* deficient strain, 5-aminolevulinic acid (50 µg/mL) was always supplemented. When necessary, 100 µg/mL ampicillin and/or 25 µg/mL chloramphenicol were supplemented.

All *B. fragilis* strains were cultivated in BHIS [Brain Heart Infusion supplemented with 5 g/L yeast extract, 1 µg/mL vitamin K1, 0.5 g/L cysteine chloride (pH=6.5), 5 µg/L hemin] or in a modified anaerobic minimal medium with glucose [AMMgluc medium; 5 g/L of glucose, 0.5 g/L cysteine chloride (pH=6.5), 0.4 g/L Na_2CO_3, 0.79 g/L $(NH4)_2SO_4$, 5% (v/v) mineral solution

stock (1.06 g/L $CaCl_2 \cdot 2H_2O$, 0.8 g/L $MgCl_2 \cdot 6H_2O$, 0.4 g/L $MnCl_2 \cdot 4H_2O$, 0.04 g/L $CoCl_2 \cdot 6H_2O$, autoclaved separately),1 µg/mL vitamin K_1, 0.5 µg/mL vitamin B_{12}, 5 µg/mL hemin, 0.4 µg/L $FeSO_4 \cdot 7H_2O$, 100 mM phosphate buffer, pH 7.2, in a gas atmosphere of 5% CO_2, 10% H_2, and 85% N_2 (Linde AG)] (Varel and Bryant 1974, Baughn and Malamy 2002). Depending on the requirement on variable K^+ concentrations, the potassium phosphate was replaced by same mole of sodium phosphate. For growth of *thyA* deletion *B. fragilis* mutants, 50 µg/mL of thymine was additionally provided. Cultivation of *B. fragilis* was carried out in an anaerobic jar or anaerobically in Hungate tubes (Hungate 1969) at 37 °C. When necessary, 50 µg/mL gentamicin, 2 µg/mL tetracycline and/ or 100 µg/mL trimethoprim were supplemented (Baughn and Malamy 2002).

All *P. luminescens* strains were grown in casein-soya-peptone (CASO) medium at 30°C (Munch, Stingl et al. 2008). When necessary, the medium was supplemented with 25 µg/mL kanamycin.

Chromobacterium violaceum DSM 30191 was grown in LB medium at 30°C overnight for genomic DNA extraction.

Table 2: Strains and plasmids

Strain/Plasmid name	Feature	Source

P. luminescens cip$^-$ P_{cipA}-*cipA-gfp*	*P. luminescens cip*$^-$ with genomically integrated pPINT-P_{cipA}-cipA-gfp.	This study
P. luminescens cip$^-$ P_{cipB}-*cipB-gfp*	*P. luminescens cip* $^-$ with genomically integrated pPINT-P_{cipA}-cipA-gfp.	This study
Chromobacterium violaceum DSM 30191	Type strain, Synonym ATCC 12472, NCTC 9757.	DSMZ
pBAD18	Ap^R, pBR322 ori, *araBAD* promoter, *araC*	(Guzman, Belin et al. 1995), lab stock
pBAD24	Ap^R, pBR322 ori, *araBAD* promoter, *araC*	(Guzman, Belin et al. 1995), lab stock
pBAD33	Cm^R, pACYC ori, *araBAD* promoter, *araC*	(Guzman, Belin et al. 1995), lab stock
pBAD-gfp	pBAD18 vector harboring *gfp* gene	Lab stock
pBAD18	pBR322 ori, *araBAD* promoter, *araC*, Ap^R.	(Guzman, Belin et al. 1995), lab stock
pNBU1	*E. coli – B. fragilis* shuttle vector, Ap^R, Em^R. The intN1 tyrosine integrase encoded on the vector catalyzes the recombination between the attN site of pNBU1 and one of two attBT sites on the *B. fragilis* chromosome.	(Wang, Wang et al. 2001, Mimee, Tucker et al. 2015)
pYT102	p15A *ori*, RP4 *oriT*; *B. fragilis* suicide vector, *thyA*$^+$, Cm^R,Tet^R.	(Meehan, Baughn et al. 2012)
pJST61	*E. coli – B. fragilis* shuttle vector, pBR322 *oriV*, pRK2 *oriT,* with *endRI* under the control of the promoter of phage lambda, Em^R, Ap^R.	(Meehan, Baughn et al. 2012)
pBAD-rrK+	The gene (*rr*$^{K+}$) encoding the putative response regulator of Kdp system is expressed from P_{BAD} on the pBAD18 backbone, Ap^R. Six-histidine codons are added to the 5' terminus of the *rr*$^{K+}$ gene (locus: BF9343_0503).	This study
pBAD-hkK+	The gene (*hk*$^{K+}$) encoding the putative histidine kinase of Kdp system is expressed from P_{BAD} on the pBAD18 backbone, Ap^R. Six-histidine codons was added to the 3' terminus of the *hk* gene (locus: BF9343_0509).	This study
pBAD-rrK+-hkK+	The genes *rr*$^{K+}$ and *hk*$^{K+}$ are express from P_{BAD}, pBAD18 backbone.	This study
pBAD-rrK+-hkK+-kdpD	The genes *rr*$^{K+}$ and *hk*$^{K+}$ and *kdpD* are expressed from P_{BAD}, pBAD18 backbone, Ap^R. Six-histidine codons are add to the 5' of the *rr*$^{K+}$ gene and to the 3' terminus of the *hk*$^{K+}$ and *kdpD* (locus: BF9343_0508) genes, respectively.	This study
pNBU1-PKdp-NanoLuc	Nanoluc luciferase gene is expressed from the native P_{Kdp} of *B. fragilis* NCTC 9343, pNBU1 backbone.	By Mark Mimee
pNBU1-PKdp(mu)-NanoLuc	Nanoluc luciferase gene is expressed from mutated (putative -12 and -24 motifs are mutated) P_{Kdp} of *B. fragilis* NCTC 9343, pNBU1 backbone.	This study
pYT102-ΔthyA	Vector for gene deletion of *thyA* (gene locus BF9343_3430), pYT102 backbone.	This study

Strain/Plasmid name	Feature	Source
pYT102-ΔrrK+	Vector for gene deletion of *rr*$^{K+}$, pYT102 backbone	This study
pYT102-ΔkdpA	Vector for gene deletion of *kdpA* (*kdpA* gene locus BF9343_0504), pYT102 backbone.	This study
pYT102-ΔkdpO	Vector for gene deletion of *kdpO* (*kdpO* gene locus BF9343_0507), pYT102 backbone.	This study
pYT102-ΔkdpD	Vector for gene deletion of *kdpD*, pYT102 backbone.	This study
pYT102-ΔhkK+	Vector for gene deletion of *hk*$^{K+}$, pYT102 backbone	This study
pPV5-3 R511Q-6His	Vector for protein overproduction of *E. coli* KdpD-R511Q-6His, Ap^R, P_{tac} pBR322 origin.	(Jung and Altendorf 1998), lab stock
pBAD24/HS	pBAD24 backboned vector carrying a gene mutant encoding *E.coli* KdpD ΔTM1-4-6His (KdpD soluble mutant). Construction of pBAD24-KdpD-WrbA-6His is based on this vector	Lab stock
pBAD24-KdpD-WrbA-6His	Vector for protein overproduction of *E. coli* KdpD-WrbA-6His, pBAD24 backbone	This study
pBD (1-395)/6his	Vector for protein overproduction of *E. coli* KdpD 1-395-6His, pBAD18 backbone	(Heermann, Altendorf et al. 2000), Lab stock
pBD2 DeinoD-6His	Vector for protein overproduction of *D. radiodurans* KdpD-6His. This KdpD protein is naturally "truncated" KdpD.	Lab stock
pBD5-3	pBAD18 backboned vector with *kdpD* gene under the control of arabinose promoter. Used as template for *E. coli kdpD* gene fragment PCR amplification.	(Jung, Heermann et al. 1998), lab stock
pKJ2-6His	Vector for protein overproduction of *E. coli* KdpD-6His, Ap^R, P_{tac} , pKK223-3 backbone.	(Jung, Tjaden et al. 1997), lab stock
pBAD24-KdpD(Met+38-380)-6His	pBAD24 backboned vector for protein overproduction of *E. coli* KdpD (38-380)-6His, which wasidentified as stable fragemt by limited proteolysis. "ATG" start codon was added in front of the codon of KdpD 38T.	This study
pMSP1E3D1	pET 28a backboned vector, Km^R, T7_promoter	(Denisov, Baas et al. 2007)
pNPTS-138-R6KT	versatile suicide vector.	(Lassak, Henche et al. 2010)
pNPTS-138-R6KT-del-cipA	pNPTS-138-R6KT containing regions homologous to upstream and downstream of the *P. luminescens cipA*, designed for clean deletion of *cipA*.	This study
pNPTS-138-R6KT-del-cipB	pNPTS-138-R6KT containing regions homologous to upstream and downstream of the *P. luminescens cipB*, designed for clean deletion of *cipB*.	This study
pPINT	pNPTS-138-R6KT containing *rpmE* and *glmS* homologous regions of the *P. luminescens*, designed for gene integration into *P. luminescens* genome.	(Glaeser and Heermann 2015)
pPINT-P_{cipA}-cipA-gfp	pPINT containing overlap PCR product of P_{cipA}-*cipA-gfp,* designed for *cipA-gfp* integration into *P. luminescens cip*$^-$ genome.	This study
pPINT-P_{cipB}-cipB-gfp	pPINT containing overlap PCR product of P_{cipB}-*cipB-gfp,* designed for *cipA-gfp* integration into *P. luminescens cip*$^-$ genome.	This study
pFasBac1	Vector for protein productions in insect cells using the baculovirus system.pUC origin, pH promoter (Polyhedrin promoter) Ap^R ,Gm^R	Thermo Fisher Scientific
pFastBac1-cipA-gfp	pFastBac1 backoned, for expression of *cipA-gfp* gene fusion from, pH promoter.	This study
pFastBac1-cipB-gfp	pFastBac1 backoned, for expression of *cipB-gfp* gene fusion from, pH promoter.	This study
pBAD-6his-lacZ	pBAD18 vector harboring *E. coli* derived *lacZ* gene, with 6 histidine codons fused to the 5' end of *lacZ*.	Lab stock
pBAD-cipA-6his	pBAD18 vector harboring c*ipA* gene with 6 histidine codons at its 3' end.	This study
pBAD-cipB-6his	pBAD18 vector harboring c*ipB* gene with 6 histidine codons at its 3' end.	This study

Strain/Plasmid name	Feature	Source
pBAD-gfp-cipA	pBAD18 vector harboring the gene hybrid *gfp-cipA*.	This study
pBAD-gfp-cipB	pBAD18 vector harboring the gene hybrid *gfp-cipB*.	This study
pBAD-cipA-gfp	pBAD18 vector harboring the gene hybrid *cipA-gfp*.	This study
pBAD-cipB-gfp	pBAD18 vector harboring the gene hybrid *cipB-gfp*.	This study
pBAD-cipA-lacZ	pBAD18 vector harboring the gene hybrid *cipA-lacZ*.	This study
pBAD-cipB-lacZ	pBAD18 vector harboring the gene hybrid *cipB-lacZ*.	This study
pBAD-cipA-(gfp,lacZ)	pBAD18 vector harboring the hybrids *cipA-gfp and cipA-lacZ*.	This study
pBAD-cipB-(gfp,lacZ)	pBAD18 vector harboring the hybrids *cipB-gfp and cipB-lacZ*.	This study
pBAD-free-(vioA,vioB)	pBAD18 vector harboring the genes of *vioA* and *vioB*.	This study
pBAD-cipA-(vioA,vioB)	pBAD18 vector harboring the hybrids of *cipA-vioA* and *cipA-vioB*.	This study
pBAD-free-(vioC,vioD,vioE)	pBAD33 vector harboring the genes of *vioC*, *vioD* and *vioE*.	This study
pBAD-free-(vioC)-cipA-(vioD,vioE)	pBAD33 vector harboring the gene of *vioC*, and hybrids of *cipA-vioD* and *cipA-vioE*.	This study
pBAD-cipA-(vioC,vioD,vioE)	pBAD33 vector harboring the hybrids of *cipC-vioC*, *cipA-vioD* and *cipA-vioE*.	This study
pBAD-cipA(1-47)-gfp	pBAD18 vector harboring the gene hybrid *cipA(1-47)-gfp*.	This study
pBAD-cipA(1-32)-gfp	pBAD18 vector harboring the gene hybrid *cipA(1-32)-gfp*.	This study
pBAD-cipA(1-23)-gfp	pBAD18 vector harboring the gene hybrid *cipA(1-23)-gfp*.	This study
pBAD-cipB(1-59)-gfp	pBAD18 vector harboring the gene hybrid *cipB(1-59)-gfp*.	This study
pBAD-cipB(1-33)-gfp	pBAD18 vector harboring the gene hybrid *cipB(1-33)-gfp*.	This study
pBAD-cipB(1-17)-gfp	pBAD18 vector harboring the gene hybrid *cipB(1-17)-gfp*.	This study

2.2.3 Plasmid construction

Plasmids used in this study are listed in Table 2, and the primers used for PCR amplification of the DNA fragments needed to generate these plasmids are listed in Table 3. All gene fusions (*e.g.* the Δ*thyA*-gene fusion composing two DNA fragments homologous separately to upstream and downstream of *thyA* gene. It was generated for *thyA* gene deletion) were created with overlap PCR.

To construct plasmids pBAD-rrK+, pBAD-hkK+, pBAD-rrK+-hkK+, pBAD-rrK+-hkK+-kdpD, pYT102-ΔthyA, pYT102-ΔrrK+, pYT102-ΔkdpA, pYT102-ΔkdpO, pYT102-ΔkdpD and pYT102-ΔhkK+, the respective genes or gene fusions were amplified using chromosomal DNA of *B. fragilis* NCTC 9343 as template. The amplified DNA fragments were then digested and ligated into the correspondingly restricted vector pBAD18 (Guzman, Belin et al. 1995) or pYT102 (Meehan, Baughn et al. 2012).

Plasmid pNBU1-PKdp-NanoLuc was created by placing the luciferase gene *Nluc* under the control of *B. fragilis kdp* promoter $P_{kdpB.\ fragilis}$. pNBU1-PKdp(mu)-NanoLuc was created from pNBU1-PKdp-NanoLuc by replacing the native promoter with a mutant (wild type, TGGCACGCATTTGGCAT; mutant, TAATACGCATTTAATAT) to destroy the predicted σ^{54} recognition motif.

To construct the *kdpD-wrbA* gene fusion, *wrbA* gene was amplified with *E. coli* MG1655 genome DNA with the primers listed in Table 3. Fragments of *kdpD* upstream and downstream of the first periplasmic loop coding regions were amplified separately with pBD5-3 as the template. Subsequently, these two fragments were fused to upstream and downstream of the amplified *wrbA* gene via overlap PCR. To generate the pBAD24-KdpD-WrbA-6His (for overproduction of KdpD-WrbA-6His), the produced *kdpD-wrbA* gene fusion was digested with *Sac*I and *Nde*I and ligated into equally treated pBAD24/HS vector backbone. To generate pBAD24-KdpD(Met+38-380)-6His, *kdpD* gene fragment encoding KdpD 38-380 (identified as stable fragment via limited proteolysis and sequenced via mass spectrometry) was amplified with pBD5-3 as template and ligated into pBAD24 vector after restriction.

To create pPINT-P_{cipA}-cipA-gfp and pPINT-P_{cipB}-cipB-gfp, P_{cipA}-*cipA-gfp* or P_{cipB}-*cipB-gfp* (synthesized by overlap PCR; P_{cipA} or P_{cipB} stands for the native promoters of *cipA* and *cipB*) was ligated into the pPINT vector (Glaeser and Heermann 2015). Gene fusions *cipA-gfp* and *cipB-gfp* were amplified from pPINT-P_{cipA}-cipA-gfp and pPINT-P_{cipB}-cipB-gfp with primers Insect CipA- BamHI-Sense/Insect CipB-BamHI-sense and gfp-HindIII-anti (see Table 3) and ligated into pFastBac1 to creat pFastBac1-cipA-gfp and pFastBac1-cipB-gfp. To generate plasmid pBAD-cipA-6His, pBAD-cipB-6his, pBAD-gfp-cipA, pBAD-gfp-cipB, pBAD-cipA-gfp, pBAD-cipB-gfp, pBAD-cipA-lacZ, and pBAD-cipB-lacZ, pBAD-cipA(1-47)-gfp, pBAD-cipA(1-32)-gfp, pBAD-cipA(1-23)-gfp, pBAD-cipB(1-59)-gfp, pBAD-cipB(1-33)-gfp, pBAD-cipB(1-17)-gfp, the respective genes or gene fragments were amplified using chromosomal DNA of *P. luminescens*, *E. coli* or pBAD-gfp as template. Gene fusions were constructed by overlap PCR.

Herein, His-tag was added to the N-terminus of LacZ and to the C-terminus of CipA and CipB, respectively. The DNA fragments were then digested and ligated into the correspondingly resected vector pBAD18 (Guzman, Belin et al. 1995). Plasmids pBAD-cipA-(gfp,lacZ) and pBAD-cipB-(gfp,lacZ) were generated by successively ligating *cipA-gfp* and *cipA-lacZ* or *cipB-gfp* and *cipB-lacZ* into pBAD18. To generate the pBAD-free-(vioA,vioB) and pBAD-cipA-(vioA,vioB) constructs, *vioA* and *vioB* genes or c*ipA-vioA* and *cipA-vioB* fusions were amplified from chromosomal DNA of *P. luminescens* or *C. violaceum* DSM 30191. DNA fragments were digested and then ligated successively into the appropriately digested pBAD18. In the same way, pBAD-free-(vioC,vioD,vioE), pBAD-free-(vioC)-cipA-(vioD,vioE) and pBAD-cipA-(vioC,vioD,vioE) plasmids were constructed by successively ligating *vioC*, *vioD* and *vioE* genes, either alone or as c*ipA-vioC*, *cipA-vioD*, *cipA-vioE* fusions, into the pBAD33 vector (pBAD18 compatible) (Guzman, Belin et al. 1995).

Unless specified, all restriction digests of PCR-amplified DNA fragments and pBAD18, pBAD24, pBAD33, pNBU1 and pYT102 vectors were performed with the enzymes indicated in the names of the primers used for gene amplification (Table 3). All multiple genes or gene fusions ligated into common vectors can be expressed by induction of the arabinose-dependent P_{BAD} promoter encoded on the vector backbone, but retain their own Shine-Dalgarno sequences and stop codons. Note that, in every case where a protein was tagged with a Cip scaffold, no intervening linker of any kind was used. While flexible glycine-serine linkers “GGSGGSG” were added to the two interfaces between WrbA and KdpD proteins.

2.2.4 Strain construction

2.2.4.1 Construction of *E. coli* reporter for testing *B. fragilis* Kdp system

An *E. coli* reporter strain was constructed by the method described (Fried, Lassak et al. 2012), to place the native chromosomal *lacZ* under the control of *B. fragilis kdp* promote $P_{kdp\ B.fragilis}$. Briefly, the fragment containing $P_{kdp\ B.fragilis}$ was amplified with the primers LacI-Pkdp-sen and Pkdp-lacZ-anti (see Table 3) from the genomic DNA and electro-transformed into *E. coli* LF2 to replace the P_{lac}::*rpsL-neo-kan*, cassette to generate *E. coli* YW1. Then the native *kdpD* and *kdpE* gene in the *E. coli* YW1 were deleted together with the method described in Quick & Easy *E. coli* Gene Deletion Kit (Gene Bridges), to generate the finial reporter strain *E. coli* YW2.

2.2.4.2 Conjugation of shuttle vectors from *E. coli* to *B. fragilis* and gene deletions in *B. fragilis*

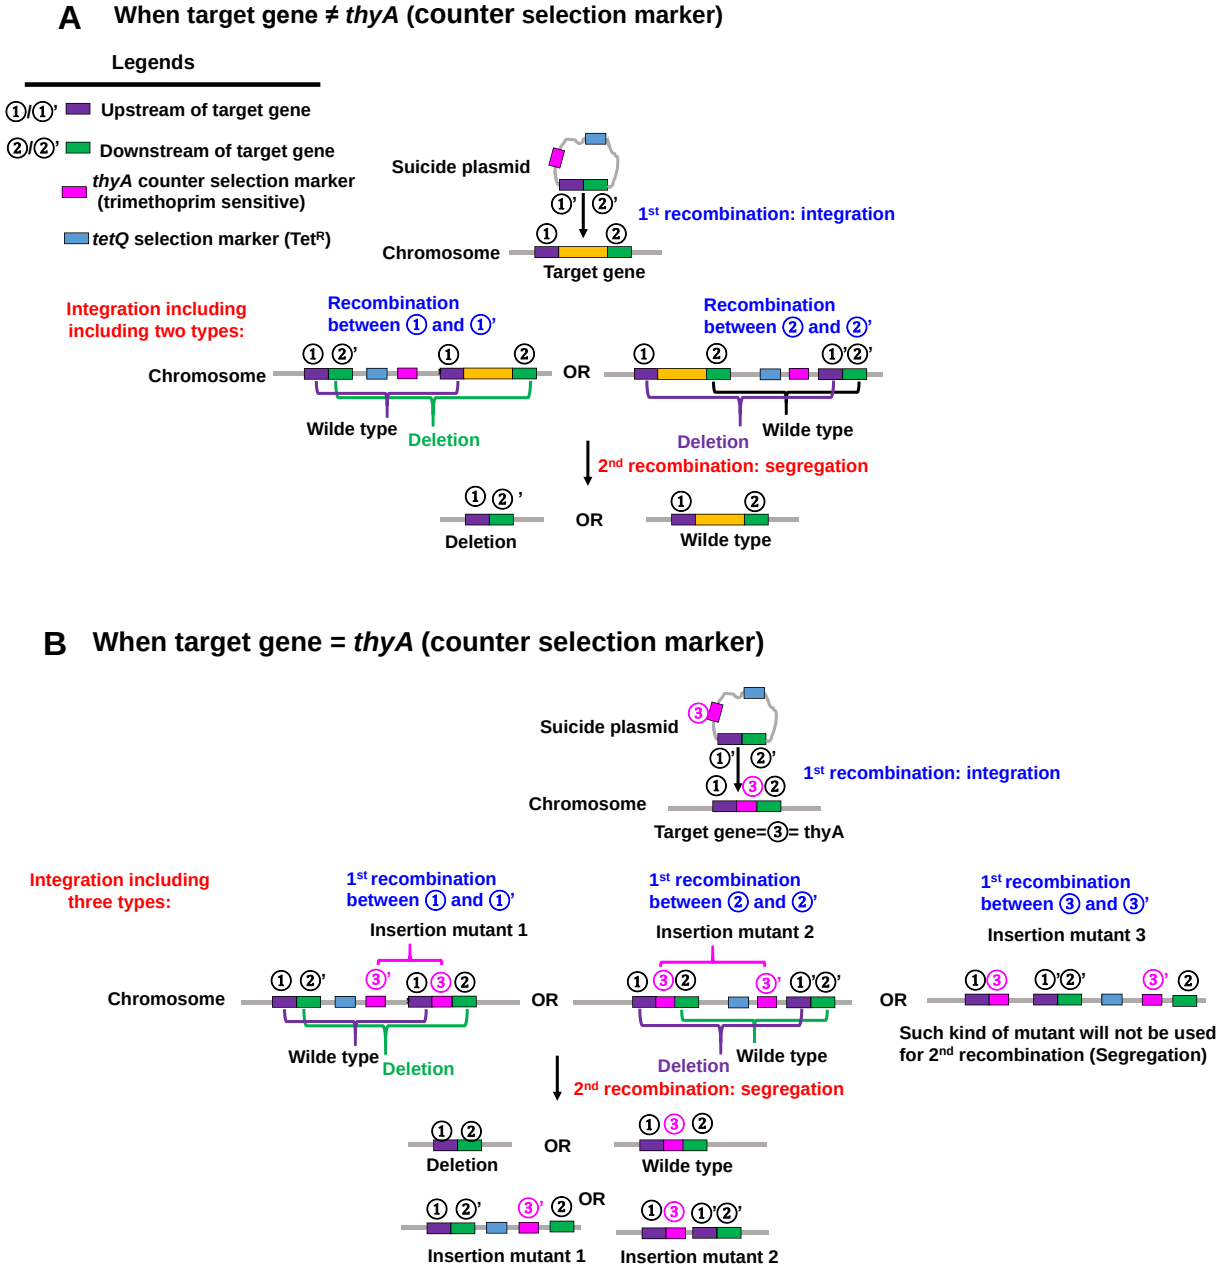

Figure 6: Schematics of gene deletion in *B. fragilis* with pYT102 backboned plasmids. (A) Deletion of a gene in *B. fragilis thyA* mutant stain. **(B)** Deletion of chromosomal *thyA* gene from the wild type strain *B. fragilis* NCTC 9343 with pYT102-ΔthyA. Gene deletion of *thyA* has priority than any other gene deletion steps, to make the counter selection work properly.

Plasmids backboned with pNBU1 were mobilized from *E. coli* ST18 (or *E. coli* S17-1 λpir) to *B. fragilis* strains by biparental mating (Choi, Herrou et al. 2016). Briefly, *E. coli* strains harboring desired plasmids were cultivated in LB medium overnight from single colony. Preculture was transfer to fresh LB and cultivated to the early exponential stage. *B. fragilis* was inoculated into BHIS and overnight culture was transferred to fresh BHIS and cultivated to the late exponential stage. Pellet 250 µL of *E. coli* and *B. fragilis* at 5,000×*g* for 5 minutes and washed once with BHIS. Mixture of them was resuspended with 50 uL fresh BHIS and spotted on BHIS plate without antibiotics (5-aminolevulinic acid and thymine is required by *E. coli* ST18 and *B. fragilis thyA* deletion mutants, respectively) and incubated anaerobically overnight at 37 °C. The lawn was collected, resuspended with BHIS and plated on BHIS containing gentamicin and erythromycin or tetracycline, and grown anaerobically. Integration of the vector was confirmed by colony PCR. The *B. fragilis* WLu reporter was constructed in such a way.

When the shuttle vectors (pYT102 backboned vectors) were designed for gene deletion (this part of experiment is still ongoing), an additional second step recombination was performed as described (Baughn and Malamy 2002). Cointegrants from the first step of recombination were grown anaerobically in BHIS supplemented with thymine (gene deletion of *B. fragilis* should be carried out in a *thyA* mutant). Overnight cultures were plated on AMMgluc plate containing thymine and trimethoprim to select for segregation of the vector and deletion of the target gene (Figure 6A).

However, to make the counter-selection (*thyA* as the marker) work properly, all the gene deletions should be carried out in *thyA* mutants. Therefore, *thyA* gene should be deleted before the deletions of *kdpA*, *kdpD*, *rr*$^{k+}$ *etc.* Principally, *thyA* mutant could be obtained by random mutation, as well as by gene deletion with the pYT102 back-boned plasmids. One may ask how the chromosomal *thyA* gene could be deleted by using the pYT102 *thyA* as counter selection marker. Even though the recombination procedures are more complicated and trickier, this is theoretically indeed possible (Figure 6B).

2.2.4.3 Construction of *P. luminescens* Δ*cipA* and/or Δ*cipB* and CipA-GFP or CipB-GFP production strains

To generate a clean deletion of *cipA* or *cipB* in *P. luminescens*, two 700-bp fragments homologous to the upstream and downstream regions of the *cipA* and *cipB* genes, respectively, were amplified using *P. luminescens* chromosomal DNA and the appropriate primers listed in Table 3. The resulting products were then combined into one DNA fragment via a second PCR step, and inserted into the suicide vector pNPTS-138-R6KT(Lassak, Henche et al. 2010) to obtain pNPTS-138-R6KT-del-cipA and pNPTS-138-R6KT-del-cipB, respectively. *E. coli* ST18 (Thoma and Schobert 2009) transformed with these plasmids was used for conjugation of *P. luminescens* TT01, and chromosomal integrants were selected on the basis of their kanamycin resistance (Glaeser and Heermann 2015). These cells were grown in CASO medium and then plated on CASO agar containing 10% (w/v) sucrose in the absence of kanamycin to select for segregation of the plasmid backbone from the chromosome. Single colonies were tested for deletion of *cipA* or *cipB* and loss of the marker gene *sacB*, which confers sucrose sensitivity (Blomfield, Vaughn et al. 1991). The overall principals are quite similar as shown in Figure 6. *P. luminescens cip*$^-$ was generated by successive deletion of *cipA* and *cipB,* and each recombination step was confirmed by colony PCR. Plasmids pPINT-P_{cipA}-cipA-gfp and pPINT-P_{cipB}-cipB-gfp were separately conjugated from *E. coli* ST18 into *P. luminescens cip*$^-$ and integrated into the genome as described (Glaeser and Heermann 2015). Recombination events were verified by colony PCR.

2.2.4.4 Construction of the strains *E. coli* Vio1 to Vio6

Violacein production strains *E. coli* Vio1 to Vio6 were generated by co-transformation of *E. coli* DH5α with the respective pBAD18 and pBAD33 derivatives containing free or *cipA*-fused *vio* genes as listed in Table 2. For use as a negative control strain for violacein production, *E. coli*

Vio0 was obtained by co-transformation of *E. coli* DH5α with the empty vectors pBAD18 and pBAD33.

2.2.5 Test the reporter strains to different signals

2.2.5.1 Fuctional analysis of KdpD-WrbA-6His in *E. coli* reporter HAK006

To test the functional performance of KdpD-WrbA-6His in comparison with the wild type KdpD, *E. coli* HAK006 transformed with pBD5-3 or pBAD24-KdpD-WrbA-6His were cultivated at 37 °C in phosphate-buffered minimal medium containing different concentrations of K^+ (Epstein and Kim 1971) for about seven hours. After measuring OD_{600}, cells were collected and frozen at -20°C. β-Galactosidase activities were measured as described (Miller 1972, Schramke, Laermann et al. 2017). β-Galactosidase activity per OD_{600} was used to demonstrate the expression level of *kdp* operon.

2.2.5.2 Test the *E. coli* reporter of *B. fragilis* Kdp system

Reporter strain *E. coli* YW2 was transformed respectively with pBAD18, pBAD-rr, pBAD-hk, pBAD-rr-hk, pBAD-rr-hk-kdpD. These strains were then cultivated at 37 °C in phosphate-buffered minimal medium containing various K^+ concentrations (Epstein and Kim 1971). When testing the response of strains to osmostress or salt stress, different amounts of sucrose (0 M, 0.2 M, 0.4 M, 0.6 M, 0.8 M) or NaCl (0 M, 0.1 M, 0.2 M, 0.3 M, 0.4 M) were added to the same minimal medium with K^+ adjusted to 10 mM. To demonstrate the transcription level of *B. fragilis kdp* operon in the reporter strain, β-galactosidase activity were assayed as described (Miller 1972, Schramke, Laermann et al. 2017).

2.2.5.3 Test the *B. fragilis* WLu reporter strain to different signals

B. fragilis WLu was cultivated overnight at 37 °C in **(i)** AMMgluc containing 0.1 mM, 1 mM, 2.5 mM, 7.5 mM, 10 mM, or 100 mM K^+ to test the response of its Kdp system to K^+ and **(ii)** AMMgluc (10mM K^+) supplemented with 0.1 M, 0.2 M, 0.4 M NaCl or with 0.2 M, 0.4 M, 0.6 M

and 0.8 M sucrose to test the response of its Kdp system to salt stress or osmostress, respectivly. Briefly, *B. fragilis* WLu was cultivated in the media described above for 9 hours. After measuring of the OD_{600}, cells were lysed and the released luciferase was mixed up with the substrate of Nano-Glo Luciferase Assay kit. Luminescence intensity per OD_{600} was used as measure for the transcriptional level of *kdp* operon.

2.2.6 Isolation of total RNA, cDNA synthesis and qRT-PCR

B. fragilis NCTC 9343 was cultivated at 37 °C in AMMgluc containing 0.1 mM or 10 mM K^+ for about 14 hours. Cells were collected and total RNA was extracted as described (Aiba, Adhya et al. 1981). The total RNA was treated with DNase to remove any genomic DNA contamination.

Subsequently, random hexamers and the isolated RNA were used to synthesize the first strand of cDNA with the RevertAid H Minus First Strand cDNA Synthesis Kit (Thermo Fisher). The relative levels of cDNA *rr*$^{K+}$, *kdpA*, *kdpC*, *kdpO*, *kdpD* and *hk*$^{K+}$ in different samples were measured with iQ™ SYBR® Green Supermix (Bio-Rad) and *recA* gene was chosen as the reference.

2.2.7 Purification of *kinase* KdpD protein

Production of wild type KdpD-6His, KdpD-R511Q-6His and KdpD-WrbA-6His was carried out with *E. coli* BL21 (DE3). Production of these proteins was induced with 0.25 mM of IPTG or 0.3% (w/v) L-arabinose (when cell density reached OD_{600} ~1.0) for three hours at 37 °C or overnight (for about 16 hours) at 16 °C. Cells were collected at 4°C and lysed with high-pressure cell disruptions in the lysis buffer (50 mM Tris-HCl, pH 7.0, 10 % (v/v) glycerol, 10 mM $MgCl_2$, 1 mM DTT, and 0.5 mM PMSF, 1 µg/mL DNase). Cell debris was removed with low speed centrifugation (14,461×*g* at 4 °C for 20 min). Supernatant was transferred to ultracentrifugation (212,605×*g* at 4 °C for 20 min) to separate the cytoplasm and the cytoplasmic membrane fractions. The isolated membrane vesicles were washed and frozen at

-80 °C. KdpD protein solubilization and purification from membrane vesicles were performed as described (Jung, Tjaden et al. 1997). Protein concentration was determined with the Lowry method (Lowry, Rosebrough et al. 1951).

2.2.8 Purification of nanodiscs MSP (MSP1E3D1)

Single colony of *E. coli* BL21 (DE3) transformed with the plasmid pMSP1E3D1 was cultivated at 30°C overnight in LB medium containing 25 µg/mL kanamycin. The overnight culture was used to inoculate LB medium (supplemented with 25 µg/mL kanamycin and pre-warmed to 37°C) loaded in two 2-liter flask. To induce the production of MSP1E3D1, 0.5 mM IPTG was added when cell density reached OD_{600} ~1.0. One hour later, the temperature was shifted from 37°C to 28°C. After three hours' further cultivation at this lower temperature, cells were collected by centrifugation and stored at -80°C. Cells was lysed in 20 mM phosphate buffer with 1% (v/v) Triton X-100. Protein purification steps were performed using Ni-NTA affinity resin. MSP shows affinity to membrane fractions, therefore 1% (v/v) Triton X-100 or 50 mM Na-cholate was added to the wash buffer (40 mM Tris-HCl, pH 8.0, 0.3 M NaCl, 20 mM imidazole) (Ritchie, Grinkova et al. 2009). Protein concentration was determined by measuring the absorbance at wavelength 280 nm with PEQLAB Nano Drop ND-1000 Spectrophotometer [(molar extinction coefficient ε280 = 29,400 $M^{-1}cm^{-1}$) (Luthra, Gregory et al. 2013)].

2.2.9 Nanodiscs assembly

Preparation of the phospholipid solution and assembly of nanodiscs was carried out as described (Hornschemeyer, Liss et al. 2016). Modifications were made at the following three points, **(i)** the membrane scaffold protein used in study is MSP1E3D1; **(ii)** ratios between MSP, target protein and phospholipid were modified to 1:130 and 4:130 **(iii)** two times more β-cyclodextrin was added to remove the DM detergent wrapping KdpD proteins. Size-exclusion chromatography was performed with Superdex 200 Increase 10/300 GL column and ÄKTA Protein Purification Systems of GE Healthcare Life Sciences, by following the manufacturer's

manual and calibration instruction (Sample injection 500 µL). Peaks were detected with UV-Vis monitor. Column calibration was performed by the Gel Filtration Calibration Kit (GE Healthcare) with the protein markers, ferritin, aldolase, conalbumin, ovalbumin, carbonic anhydrase, ribonuclase and aprotinin.

2.2.10 Purification of *non-kinase* KdpD protein

E. coli KdpD 1-395-6His, *E. coli* KdpD 38-380-6His and *D. radiodurans* KdpD-6His were produced with *E. coli* BL21 (DE3). Production of these protein was induced with 0.3% (w/v) L-arabinose for three hours at 37 °C. Cells were lysed and membrane fractions were isolated as described in 2.2.8.1. *E. coli* KdpD 1-395-6His and *D. radiodurans* KdpD-6His were extracted from membrane vesicles and purified with Ni-NTA agarose affinity chromatography as described (Heermann, Altendorf et al. 2000). Protein concentration was determined with the Lowry method (Lowry, Rosebrough et al. 1951).

2.2.11 Limited proteolysis of *non-kinase* KdpD

Purified KdpD 1-395-6His (~0.5 mg/mL) was treated with 0.1, 0.01, and 0.001 mg/mL proteinase K, trypsin or subtilisin [reaction buffer, 20 mM HEPES, pH 7.5, 50 mM NaCl, 10 mM $MgSO_4$] at room temperature or on ice for 30 min, respectively. To stop the reaction, 5×SDS loading buffer was added to the proteolysis mixture and the mixtures were subsequently applied to SDS-PAGE. Under optimal conditions, proteolysis was followed in a timecourse (reaction time 15 min, 30 min, 45 min, 60 min). Stable peptides were extracted and sent to the collaborator Dr. Markus Hartl for sequence analysis by mass spectrometry.

2.2.12 Isolation and characterization of PCIs

To isolate PCIs, cells were collected by centrifugation, resuspended in ice-cold Na-phosphate buffer (20 mM sodium phosphate buffer, pH 7.0, 8.5 mM KCl), and disrupted by three passages

through a French press (Thermo IEC Laboratory Press) at 0.4 kbar. PCIs were collected by centrifugation for 15 min at 4.000×*g*, and washed three times with the same buffer (Figure 7).

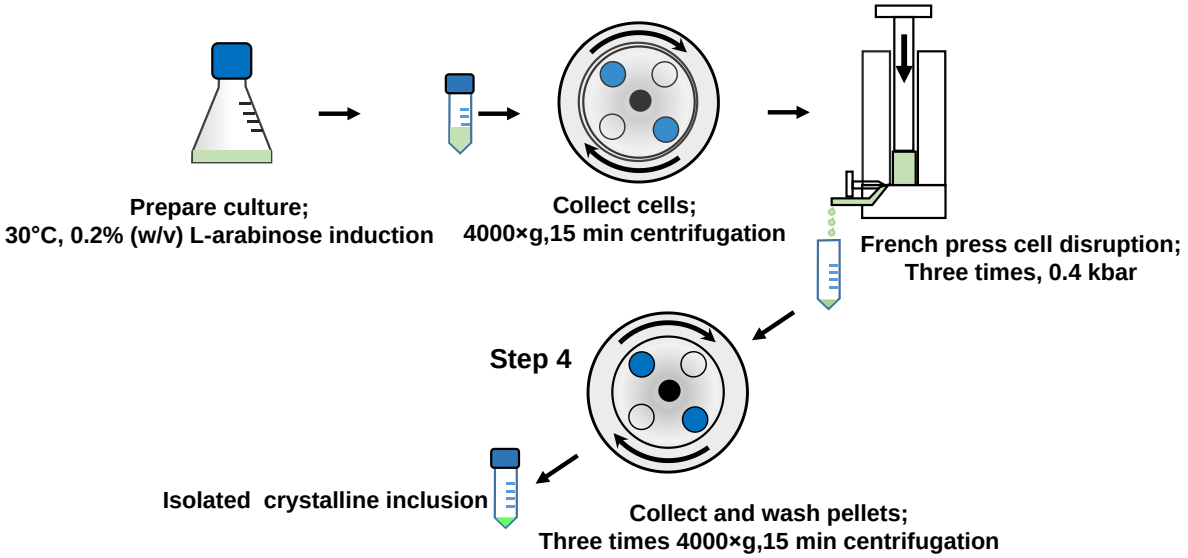

Figure 7: Schematic of production and isolation of the PCIs. Cells producing PCIs were collected by centrifugation. Cells were lysed by French press and insoluble fractions containing the PCIs were recovered by centrifugation and washed three times whith Na-phosphate buffer.

Thermal stability studies were performed in Na-phosphate buffer. The isolated CipA-GFP and CipB-GFP PCIs were incubated for 10 min at 30°C, 40°C, 50°C, 60°C, 70°C, 80°C, 90°C and 100°C, respectively, and PCIs shape and fluorescence intensity were subsequently determined by microscopy.

The solubility of PCIs was analyzed by following the method described (Bowen and Ensign 2001). CipA-GFP and CipB-GFP PCIs were resuspended at an OD_{600} of 20-60 in deionized water. Then, 10 µL of this suspension was added to, and gently mixed with 1 mL of the following solutions: **(i)** deionized water; **(ii)** 150 mM NaCl, pH 1.0, 3.0, 5.0, 7.0, 9.0, 11.0 or 13.0; **(iii)** 1 M, 2 M, 3 M, and 4 M NaCl, pH 7.0; **(iv)** 2 M, 4 M, 6 M, 8 M urea; **(v)** 100 mM EDTA, pH 7.0; **(vi)** 10% (w/v) SDS, pH 7.0; **(vii)** 100% (v/v) methanol, and **(viii)** 50% (v/v) glycerol, respectively. The OD_{600} was then monitored periodically and set in relation to that of the

corresponding control (PCIs in deionized water), which was set to 100% (Bowen and Ensign 2001).

Measuring the absorption spectra of Congo Red was performed as described (Upadhyay, Murmu et al. 2012). Briefly CipA-LacZ, CipB-LacZ, CipA-GFP&CipA-LacZ or CipB-GFP&CipB-LacZ PCIs as well as the soluble protein His-LacZ were separately diluted in reaction Na-phosphate buffer to final protein concentration of 50 µg/ml. Congo Red was added to this mixtures to a final concentration of 20 µM (Upadhyay, Murmu et al. 2012). After 30 minutes or 16 hours of incubation at room temeperature, 200 µl of these mixtures were loaded separately into 96-Well plate (Corning, Clear Bottom Black). The absorption spectra of Congo Red measured from wavelength 400 to 800 nm with Infinite M200 Plate Reader (Tecan). Congo Red alone exhibits maximum light absorbance at the wavelength of 490 nm. Upon binding to the repeated β-sheet structure in the inclusion body, its maximum light absorbance will be shifted to longer wave length of around 540 nm.

2.2.13 Overproduction, purification and assay of β-galactosidase (LacZ)

The production and isolation of CipA-LacZ or CipB-LacZ PCIs were performed as described in Figure 7. To purify LacZ in a soluble state, N-terminally 6His-tagged LacZ (His-LacZ) was produced in *E. coli* DH5α. An overnight culture (20 mL) of cells carrying pBAD-6his-lacZ was used to inoculate three 2-l flasks, each containing 500 ml of LB medium supplemented with 100 µL/mL ampicillin. When the cell density reached OD_{600} 0.8, 0.2% (w/v) L-arabinose was added to induce gene expression, and the cultures were further incubated at 37°C for 6 h. Cells were then harvested by centrifugation, suspended in lysis buffer (50 mM Tris-HCl, pH 7.0, 300 mM NaCl, 10 mM β-mercaptoethanol, 10 mM imidazole, 10 mM $MgCl_2$, EDTA-free protease inhibitor cocktail), and disrupted in a French press. Cell debris was removed by centrifugation for 20 min at 14,500×*g*, and the supernatant was loaded onto 4 ml of Ni-NTA resin previously equilibrated with binding buffer (50 mM Tris-HCl, pH 7.0, 300 mM NaCl, 10

mM β-mercaptoethanol, 10 mM imidazole, 20 mM $MgCl_2$). Columns were washed with 100 ml of washing buffer (binding buffer containing 20 mM imidazole), and His-LacZ was eluted with 20 ml of elution buffer (binding buffer containing 200 mM imidazole). Imidazole was later removed by dialysis of the protein against buffer (20 mM Tris-HCl, pH 7.0, 150 mM NaCl, 10 mM β-mercaptoethanol, 5 mM $MgCl_2$).

β-Galactosidase activity assays were performed at 30°C in modified buffer Z and quantified as described before (Miller 1972). One unit equals the amount of enzyme needed to hydrolyze 2-nitrophenyl β-D-galactopyranoside (*o*NPG) to 1 µmol of *o*-nitrophenol in 1 min at 30°C. The total protein content of PCI samples and purified His-LacZ was determined by using the Lowry method (Lowry, Rosebrough et al. 1951) Specific enzyme activity was defined as units of enzyme activity/mg of His-LacZ, or CipA-LacZ or CipB-LacZ PCIs (see the unit definition above).

To test the influence of, pH on the activity of His-LacZ, CipA-LacZ PCIs and CipB-LacZ PCIs, the, pH of modified buffer Z (chloroform and SDS were ignored) was adjusted to 5.0, 6.0, 7.0, 8.0, 9.0, and 10.0 (by adjusting the ratio between base and acid compositions), and β-galactosidase activity assays were performed at 30°C as described above. The enzyme activities measured at the different, pH values were expressed relative to the activity measured at, pH 7.0. To determine temperature dependence, the reaction temperature was adjusted to 22°C, 30°C, 37°C, 42°C, 47°C, 52°C, 57°C and 62°C, and measured activities were expressed relative to that at 30°C.

2.2.14 Western blot

For Western blot with KdpD polyclonal antiserum as the first antibody, the PVDF membrane was pre-blocked for 1 hour at room temperature with 5% (w/v) of milk powder in the buffer A (55 mM Tris-HCl, pH= 7.4, 154 mM NaCl). While for Western blot with Penta·His Antibody or anti-GFP antibody as the first antibody, the membrane was pre-blocked for 1 hour at room

temperature with 3% (w/v) of BSA in buffer A. The bands one the membrane were developed colorimetricly via the alkaline phosphatase activity of the second antibody (BCIP in conjunction with NBT as substrate) (Dejong, Vankesselvanvark et al. 1985).

2.2.15 Violacein/deoxyviolacein production and quantification

To determine the appropriate concentration of inducer for violacein production, cultures of the engineered strains (*E. coli* Vio1 to *E. coli* Vio6) in early exponential phase were diluted with LB to an OD_{600} of 0.05 and drops were placed on LB plates containing 0%, 0.01%, 0.02%, 0.05%, 0.1% and 0.4% (w/v) of L-arabinose. After overnight cultivation at 30°C, the appropriate inducer concentration was found to be in the range of 0.01% (w/v) to 0.05% (w/v) according to the pigment accumulation. The violacein production was induced with 0.01% (w/v) and 0.05% (w/v) L-arabinose.

To quantify violacein/desoxyviolacein production *E. coli* strains Vio1-Vio6 were aerobically incubated in LB medium, supplemented with 100 µg/mL ampicillin, 15 µg/mL chloramphenicol and 0.05% (w/v) L-arabinose, at 30°C. Aliquots (1 ml) were taken at the indicated time points, centrifuged, and the pellets were resuspended in 1 ml of 95% (v/v) methanol, vortexed, and cell debris was removed by centrifugation. The concentration of the violacein + deoxyviolacein mixture was determined based on absorbance at A_{577nm}, based on a molar extinction coefficient of 1.7×10^4 L mol^{-1} cm^{-1} (Sneath 1956). To determine the proportions of violacein and deoxyviolacein in the methanol extracts, a HPLC protocol was used as described (Lee, Aswani et al. 2013), but with modifications for use with the Hypersil GOLD aQ column (Thermo Scientific). Briefly, two solvents were used to perform gradient elution. Solvent A was 0.1% (v/v) formic acid in water; solvent B was 0.1% (v/v) formic acid in acetonitrile. The column was equilibrated with 95% (v/v) A + 5% (v/v) B for 6 min; 50 µL methanol extract was then injected; the solvent gradient was started 7 min after injection, and over a period of 10 min, B was increased to 98%; the 2% (v/v) A + 98% (v/v) B mixture was kept constant for 7 min and then

replaced by 95% (v/v) A + 5% (v/v) B for 2 min. Light absorbance of the peaks was analyzed with a UV/VIS detector at a wavelength of 567 nm (Lee, Aswani et al. 2013). Since pure violacein is not commercially available, a mixture of violacein (>85%) and deoxyviolacein was used as standard.

3 Results

3.1 Bioinformatics analysis on KdpD protein evolution

3.1.1 Distribution of KdpD and KdpA proteins in the three domains of life

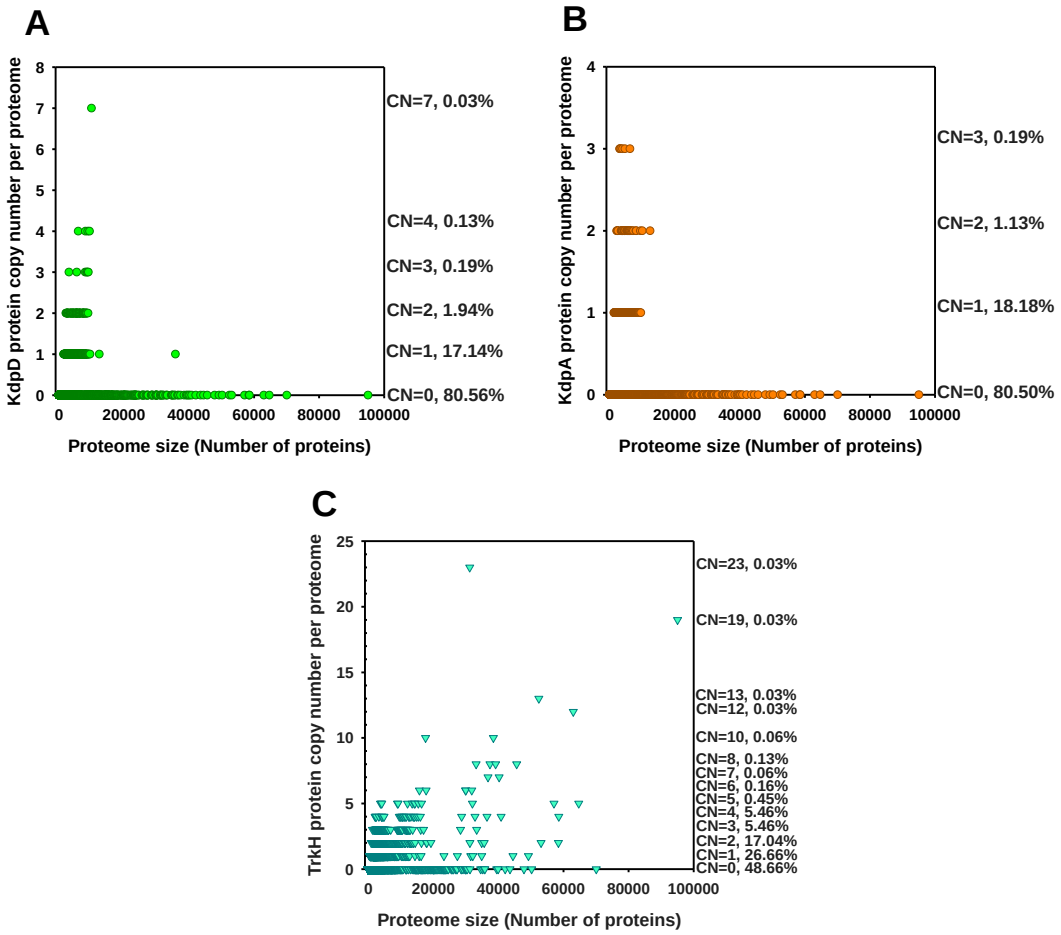

Figure 8: Abundancy of the KdpA, KdpD and the TrkH proteins in single proteomes. X-axes show the individual proteome sizes indicated by the protein numbers, while the Y-axes mark the copies of KdpD, KdpA, and TrKH proteins detected in each examined proteomes. No correlation was detected between the proteome sizes and copy numbers of KdpD, KdpA and TrkH proteins.

All proteins containing at least one KdpD domain (PF02702) were retrieved from the UniProt reference proteomes database 2015_10 (RFP) and defined as KdpD proteins (Data set-sheet 1 gives the proteome IDs and species of origin listed in the RFP database. Total number of reference proteomes for each domain of life: Archaea, 124; Bacteria, 2118; Eukaryote, 427).

In addition, all sequences of KdpA (PF03814), the translocating subunit of the inducible high-affinity K^+ transporter KdpFABC, and TrkH (PF02386), the ion channel of the constitutively expressed low-affinity transporter Trk (Figure 2), were recovered from the same database.

A total of 692 KdpD proteins were detected with HMMER 3.0 in one eukaryotic phylum (Data set-sheet 3, green rows), one archaeal phylum (Data set-sheet 3, red rows) and eighteen bacterial groups/phyla (Data set-sheet 2 and 3 black or grey rows).

Noticebaly, about 2% of all proteomes queried contained more than one KdpD or KdpA protein (all the identified KdpA protein is listed in Data set-sheet 4), while multiple TrkH (all the identified TrkH protein is listed in Data set-sheet 5) were present in about 24% of them [Figures 8 A, B and C, with copy number (CN) >1)]. No correlation between the copy number of these proteins and overall proteome size was detectable.

With one exception -- a KdpD protein (entry ID: X1X445_ACYPI) detected in the RFP of the eukaryote *Acyrthosiphon pisum* (the pea aphid) -- KdpD proteins are restricted to archaeal and bacterial proteomes.

KdpD and KdpA proteins were detected in 28.2% and 27.6% of the bacterial proteomes, respectively, and show a strong tendency to occur together in these bacterial groups/phyla, which underlines their functional relationship (Figures 9A and 9B). Frequencies of coordinated occurrence of KdpD and KdpA were lower in the phylum *Firmicutes* than in *Proteobacteria* and *Actinobacteria* (Figure 9B), implying that the coordinated function of KdpD and KdpA proteins is less important for survival in the first phylum. Notably, there is hardly any KdpD, KdpA or TrkH proteins among unclassified bacteria (Figure 9B).

In addition to their coordinated occurrence on population level, instances of coordinated occurrence and absence of KdpD and KdpA were also detected in individual bacterial proteomes. They were both present in 26.3% of individual bacterial proteomes and were both

absent in 70.5% of individual bacterial proteomes. In contrast, only a small percentage of individual bacterial proteomes contain KdpD but no KdpA (1.8%) or KdpA but no KdpD (1.3%) (Figure 9C).

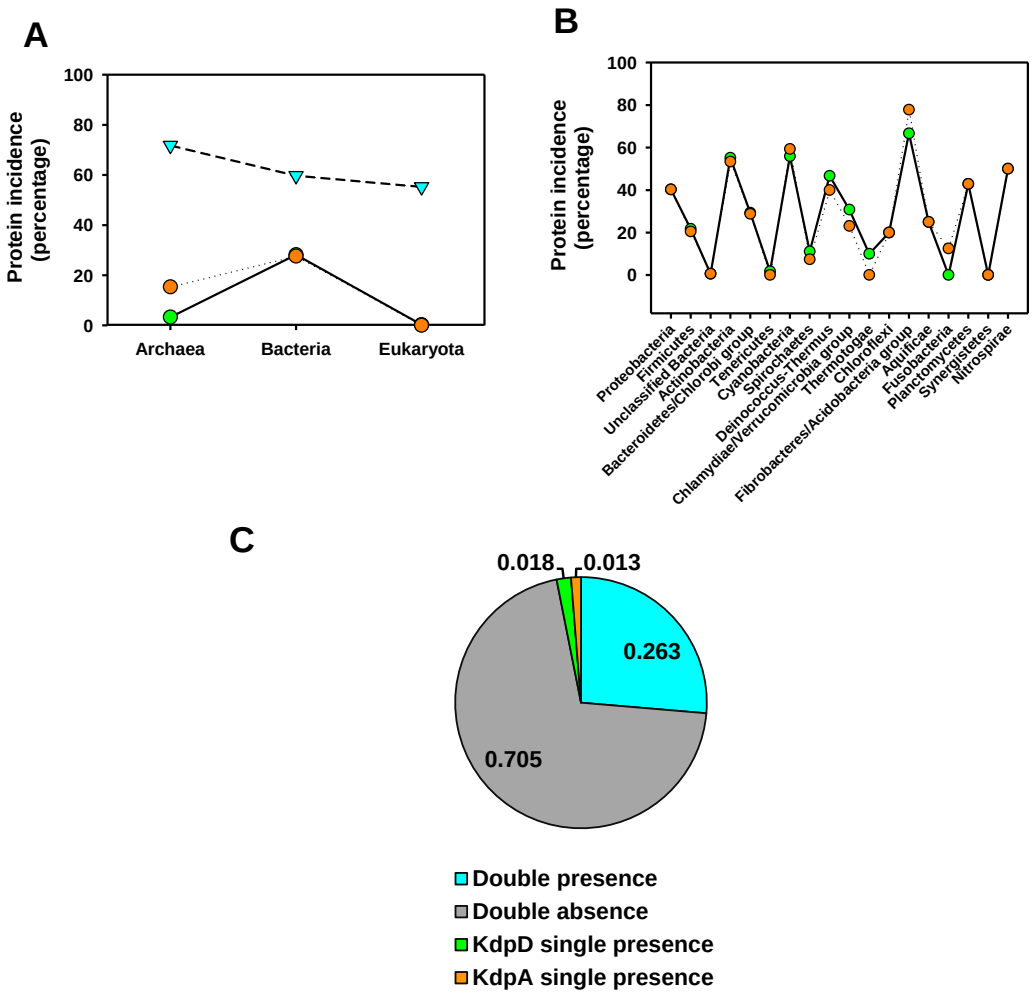

Figure 9: Coordinated distribution of KdpD and KdpA in bacterial species. Distribution of KdpD, KdpA, and TrkH proteins in reference proteomes drawn from the three domains of life. **(A)** Prevalence of KdpD, KdpA and TrkH in proteomes from the three domains of life. **(B)** Prevalence of KdpD and KdpA proteins in proteomes of the major bacterial groups/phyla (only those bacterial groups and phyla are shown that contain at least five reference proteomes): green, KdpD; orange, KdpA; cyan, TrkH. **(C)** Co-occurrence of KdpD and KdpA in individual bacterial proteomes.

In archaeal proteomes, KdpA proteins are more prevalent than KdpD proteins (Figure 9A, KdpD proteins occur in only 3.2% of proteomes, while the figure for KdpA is 15.3%). This

finding can be explained by the existence of KdpD-independent Kdp systems in this domain of life. For example, the only experimentally investigated archaeal Kdp system -- in *Halobacterium salinarum* -- does not recruit KdpD as a regulator, but employs a protein called KdpQ, which consists of two Usp domains. Although the regulatory mechanism used by KdpQ is still unclear, expression of the *kdp* operon in response to K^+ was found to be similar to that in *E. coli* (Kixmuller, Strahl et al. 2011). Genes for KdpQ homologs were also found associated with other archaeal *kdp* operons. KdpQ are actually more prevalent thank KdpD in Archaea (Figures 10 and A1, yellow colored genes marked “kdpQ”).

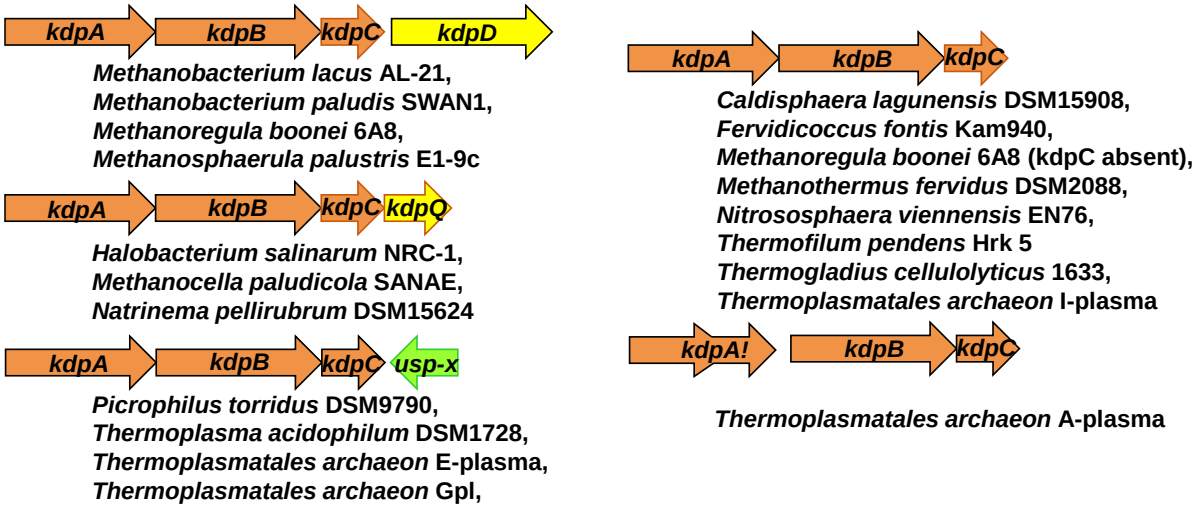

Figure 10: Genes encoding the archaeal *Kdp* systems. The species with similar *kdp* genomic neigbohoods were grouped and the species names were demonstrated under the operon icons. The *kdpD* and *kdpQ* genes were marked with yellow colors. The “*usp-x*” gene encodes a protein with domain architecture of Usp domain plus an unpredicted domain (X domain). “*kdpA!*” encodes the two parts of a split KdpA protein (due to frame shift mutation) of one KdpA protein. These two parts of KdpA were detected by HMMER as two copies of KdpA protein.

As a comparison, the distribution of TrkH proteins were also analyzed. TrkH has much wider distribution than KdpA and was observed in all the three domain of life. No correlation between the distributions of KdpD and TrkH proteins was found (Figure 9A).

Taking together the Kdp system of Archaea and Bacteria, KdpD proteins are the most common, but not the only regulator of the *kdp* operon.

3.1.2 Functional classification of KdpD proteins

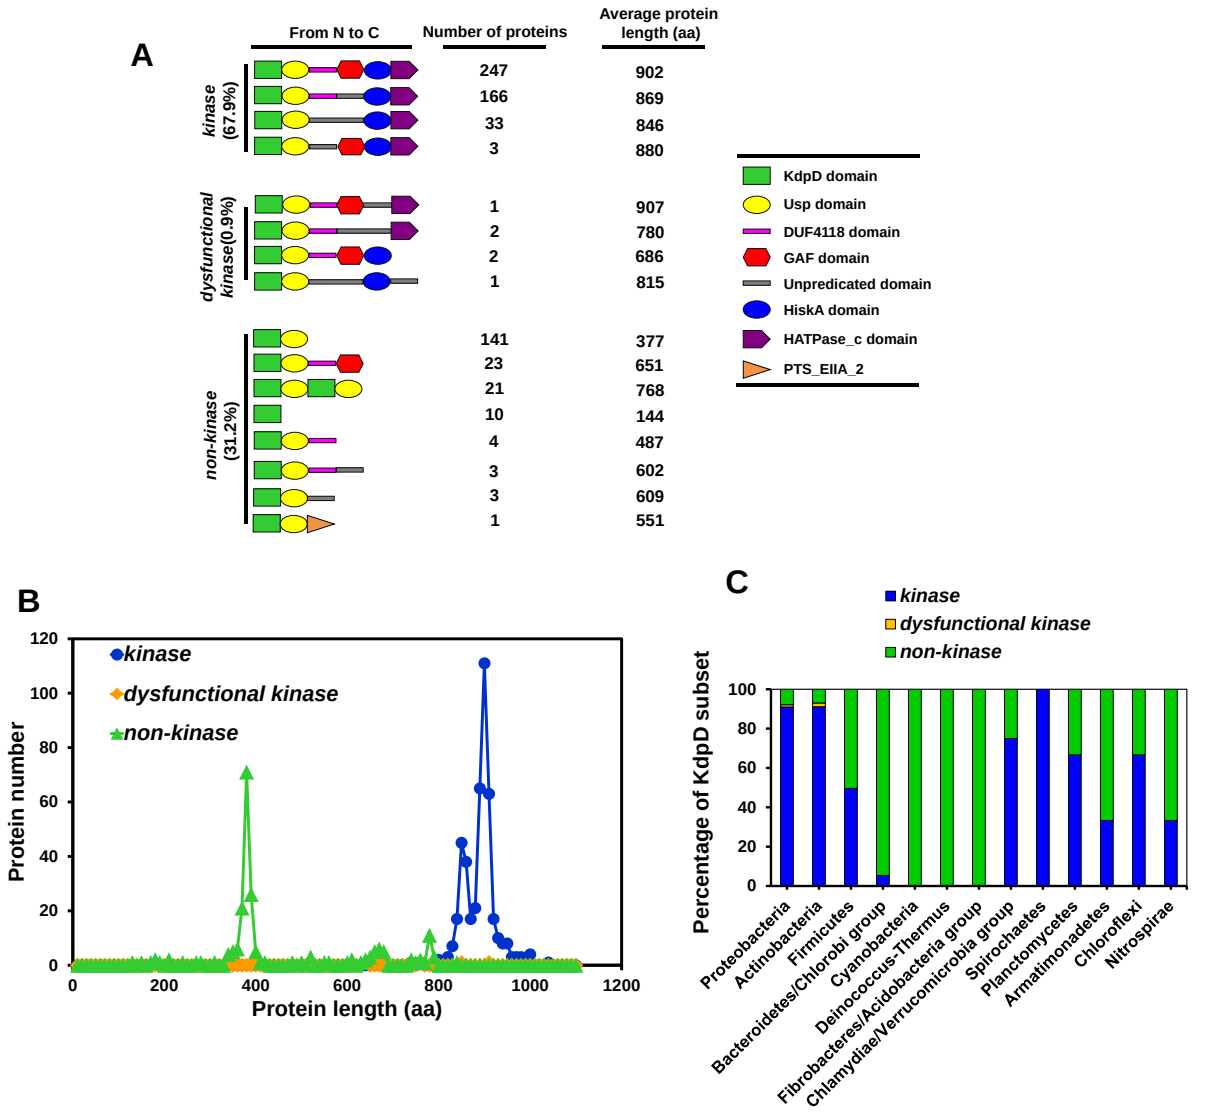

Figure 11: Functional classification of KdpD proteins according to the domain architecture of the overall proteins. (A) KdpD proteins were classified into three groups (*kinase*, *dysfunctional kinase* and *non-kinase*) on the basis of their domain architecture. **(B)** Length [in amino acids (aa)] variations of KdpD proteins. **(C)** Distribution of the three groups of KdpD proteins among bacterial groups/phyla (only those bacterial groups and phyla are shown that contain at least three KdpD proteins).

Before carrying out further analysis of the predicted 692 KdpD proteins detected by HMMER 3.0, all of them were examined with CDD v3.14 (CD-search as the interface) to annotate the domains contained in each sequence as well as refining the protein list. The cut-off *E*-value was set to 0.001, and 661 out of 692 proteins detected by HMMER 3.0 were predicted by CDD v3.14 to have at least one KdpD domain (Data set-sheet 3). These 661 proteins were retained as the refined list and their lengths, domain architectures and distributions were subsequently analyzed. Based on domain architecture, they were classified into three groups: *kinase*, *dysfunctional kinase* and *non-kinase* (Figure 11A). In terms of length, they fall into two major groups: one has 370-400 amino acids and the other consists of about 850-900 residues (Figure 11B). *Kinase*s and *non-kinase*s make up the majority of KdpD proteins, accounting for 67.5% and 31.2%, respectively, of the set surveyed here (Figure 11A).

The *kinases* necessarily contain HisKA and HATPase_c domains, *dysfunctional kinases* contain either one or the other, and *non-kinases* lack both of these domains (due to either gene truncation or the essential asparate amino acid was substituted). The KdpD of *E. coli* is a typical example of the *kinase* group, consisting of KdpD and Usp domains, the four-helix transmembrane domain (DUF4118), a GAF domain and the HisKA and HATPase_c domains.

Non-kinase KdpD proteins are usually much shorter, and include the truncated KdpD of *Anabaena* sp. strain L31, *Synechocystis* sp. strain PCC 6803 and *D. radiodurans* (Ballal and Apte 2005, Nanatani, Shijuku et al. 2015). Most of the *non-kinase* KdpD comprise two domains: KdpD-Usp. However, there are two versions of special *non-kinase* KdpD with domain architectures of KdpD-Usp-KdpD-Usp and KdpD-Usp-DUF4118-GAF, respectively (Figure 11B). As will be discussed later, these two versions of *non-kinase* KdpD are meanly found in *Firmicutes*, indicating quite diverse evolution events of their KdpD proteins.

The *dysfunctional kinase* just have six KdpD sequences. Five of them have quite similar protein length to that of the *kinase*. However, there is no predicted HiskA or HATPase_c domain in

these five KdpD, because the conserved amino acids of either of these two domains were replaced. The other *dysfunctional kinase* has shorter protein sequence (686 amino acid sequences), indicating the HATPase_c domain was deleted.

The two major groups of KdpD proteins are preferentially represented in different bacterial groups/phyla (Figure 11C). For example, the *kinase* KdpD account for more than 80% all KdpD detected in *Proteobacteria* and *Actinobacteria*, and examples of *non-kinase* KdpD are rare (Figure 11C). In contrast, KdpD were predominantly detected as *non-kinase* in the *Bacteroidetes/Chlorobi* group, *Cyanobacteria* and *Deinococcus-Thermus*. *Firmicutes* have both *non-kinase* and *kinase* KdpD at an equal proportion.

3.1.3 Lineage-specific KdpD evolution events

Having shown the distribution pattern of KdpD proteins and disparate preferences of bacterial specices for *kinase* or *non-kinase* KdpD (Figure 11B). The next step is to infer the evolution of the KdpD proteins and reveal the evolutionary relationship between the *kinase* and *non-kinase* KdpD. To reconstructed the KdpD protein tree, amino acid sequences of the predicted 682 KdpD domains and 672 Usp domains were extracted (see Figure 11A) and aligned with Mafft L-INS-i. The aligned columns with more than 95% of gaps were removed with trimAl v1.2 (Capella-Gutierrez, Silla-Martinez et al. 2009) and the aligned KdpD domains and Usp domains were concatenated. Tidy alignments were used for Maximum Likelihood tree reconstructions with the PhyML 3.0 [(LG+ estimated invariable sites + 4 substitution rate categories, branch support value was estimated with approximate likelihood ratio test (aLRT), tree topology was improved with Nearest Neighbor Interchange (NNI)] (Anisimova and Gascuel 2006, Guindon, Dufayard et al. 2010).

On the constructed Maximum Likelihood tree (Figures 12 and A2), the most distinguished feature is that the presence of horizontal gene transfer (HGT).

(i) KdpD of Archaea have short-branch length and disperse at different positions on the tree. This results indicates that the *kdpD* genes were not inherited from the common ancestor of bacteria and archaea, but rather from bacterial species, via HGT. Therefore, the archaeal KdpD proteins cannot be used to root the whole protein tree.

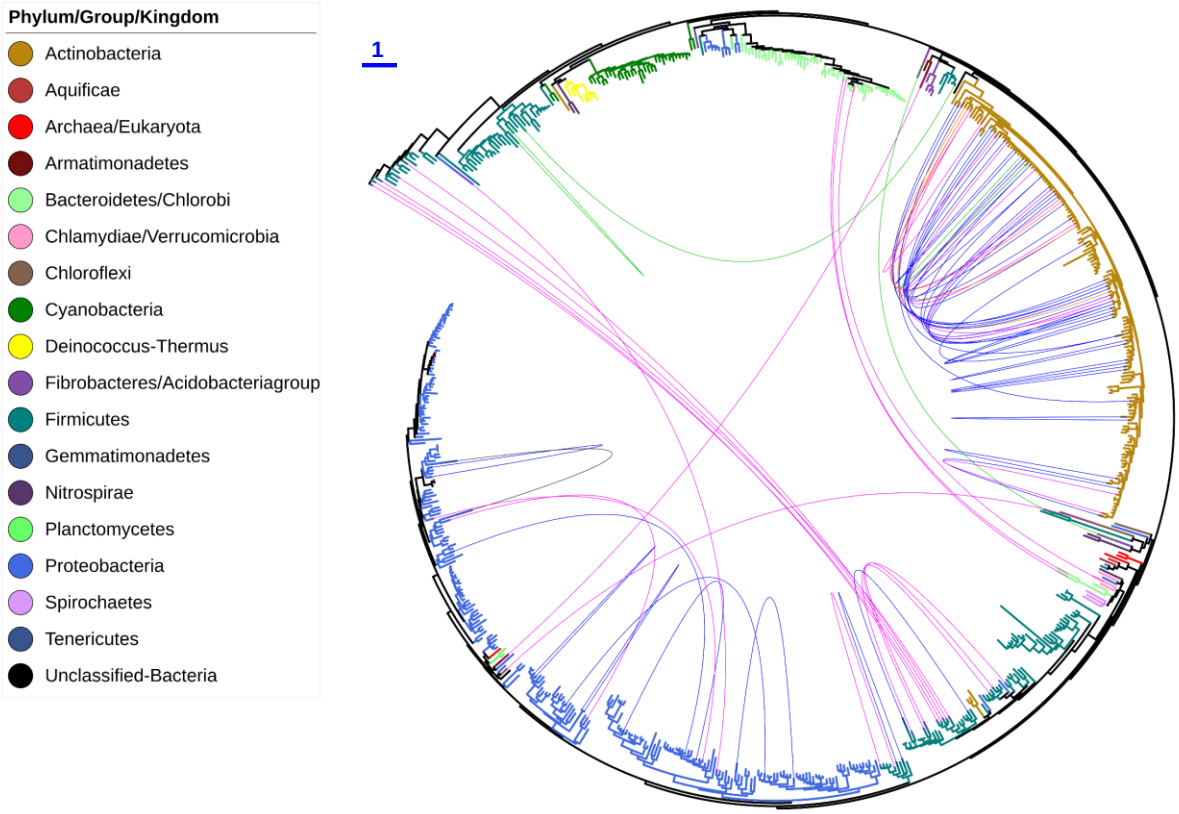

Figure 12: Unrooted Maximum Likelihood KdpD protein constructed from concatenated KdpD and Usp MSA. Color of the branches designate the bacterial phylum or group (red color branches stands for archaeal KdpD). Curves connecting KdpD proteins belong to the same species (acquire via KdpD duplication or HGT). Blues curves connecting two *kinase* KdpD; Magenta curves connecting *kinase* and *non-kinase* KdpD; Orange colors connecting *kinase* KdpD and *dysfunctional* KdpD.

(ii) *Firmicutes* do not form unique phyletic group, but two major groups and several small clusters (Figures 12 and A2). The first big group is staying together with cyanobacterial KdpD. While the second group obviously is in conflict with the life tree (see Figure 13B), interjects between *Chlamydiae/Verrucomicrobia*, *Nitrospirae* and the large proteobacterial KdpD cluster.

This group suggests the presence of either “genuine paralogs” or “pseudoparalogs” (Koonin 2005) of KdpD in *Firmicutes*. Suppose the paralogs were “genuine”, the duplication of *kdpD* genes should have occurred before the generation of *Firmicutes* divergence. In other words, this would mean subsequent widespread lose events of one of the paralogs in most of the other bacterial species, because most of bacterial phyla do not possess multi-phyletic groups. Conversely, supposed the paralogs are pseudoparalogs, the *Firmicutes* KdpD, which is sharing closer relation with *Proteobacteria*, *Chlamydiae/Verrucomicrobia* and *Nitrospirae*, should be obtained via HGT from the species appeared between the divergence of *Chlamydiae/Verrucomicrobia*, *Nitrospirae* and the prevalence of *Proteobacteria* on the earth.

(iii) Like the *Firmictues*, 50% *Deltaproteobacteria* KdpD do not form unique cluster on the proteins tree. One cluster is clamping with the KdpD of *Bacteroidetes/Chlorobi* group, which also suggests either the presence of genuine paralogs or HGT.

In addition to probable HGT, KdpD protein duplications were also observed in some species (Figures 12 and A2, KdpD proteins connected by colored curves). Moreover, duplication of KdpD are different from phylum to phylum.

(i) Duplication of KdpD is most obvious in *Actinobacteria* and almost all actinobacterial KdpD proteins are arranged into one phyletic group (Figures 12 and A2). This results indicates the KdpD duplication occurs after the *Actinobacteria* divergence or HGT within the phylum.

(ii) Inner phyletic duplication of KdpD was also found in *Firmicutes*. Moreover, some *Firmicutes* species also have multiple KdpD proteins being localized into separated two groups. As described above, this should be caused either by gene duplication or HGT.

These results suggest that KdpD proteins have quite various evolution trajectories in the bacterial species.

3.1.4 Domain shuffling (recombination) between Usp and DUF4118 domains shapes the evolution of KdpD proteins.

Evolution occurs on multiple levels with different molecular mechanism. In addition to the nucleotide insertions, deletions, substitutions, gene recombinations can speed up drastically the evolution of a gene. Gene recombination would cause rearrangements of protein domain (domain shuffling) or domain duplications, especially to the multi-domain proteins. As the basic evolution unit, protein domains have been undergoing extensive duplication and recombination during the evolution course--2/5-3/5 of the proteins in prokaryotes are composed of multiple domains (Han, Batey et al. 2007).

As shown above, 98.5% of KdpD proteins are multi-domain proteins (Figure 11A). Only 10 KdpD proteins were identified to be composed of stand-alone KdpD domain, some of which may be rather due to short-gun sequencing interruption. Interestingly, all the other KdpD domains are only connecting to the Usp domain, but not to any of the other domains. This finding indicates the strong evolutionary and functional relationship between these two domains.

In addition to the essential domains HisKA and HATPase_c, DUF4118 domain is also important to distinguish *kinase* KdpD from *non-kinase* KdpD. DUF4118 domain in *E. coli* KdpD is known essential for the K^+ sensing (Zimmann, Steinbrugge et al. 2007, Schramke, Tostevin et al. 2016). Moreover, more than 92% of *kinase* KdpD have a DUF4118 domain, while only 14.6% of the *non-kinase* KdpD contain this domain [(all such proteins exhibit KdpD-Usp-DUF4118-(X) or KdpD-Usp-DUF4118-GAF domain architectures (Figure 11B)]. This results indicates that domain shuffling between Usp domain and DUF4118 domain drastically shapes the evolution of KdpD proteins and mediates the interconversion between *kinase* and *non-kinase* KdpD.

To illustrate the evolution process of KdpD proteins, all the DUF4118 domain-containing proteins (DUF4118 proteins) were also collected with HMMER 3.0. Actually, only 51.4% DUF4118 domains are incorporated into KdpD proteins [(A protein with KdpD domain would be preferentially called KdpD protein) (Table 4 and Data set-sheet 6)]. The following table shows the diverse domain compositions of the other proportion of DUF4118 proteins, which accounts for a percentage of 48.6 % but does not fuse to KdpD and Usp domains. For simplicity, they are called “non-KdpD DUF4118 proteins”. Some of the *non-KdpD DUF4118* proteins (Table 4, rows in bold) are identical to the C-terminal of *kinase* KdpD (Figure 11B). It principally makes the interconversion between *kinase* and *non-kinase* KdpD rather sample and it does not require multiple-step recombination.

Table 4: Domain composition of *non-KdpD DUF4118 proteins*
(x stands for unpredicted domain)

Theoretical routes of domain shuffling between the KdpD-Usp and DUF4118 proteins, which support the interconversion between *kinase* KdpD and *non-kinase* KdpD were proposed (Figure 13A). Additionally, KdpD domain was duplicated in some *non-kinase* KdpD. It is a process independent of the DUF4118 proteins and results in the KdpD variants with the domain architecture of KdpD-Usp-KdpD-Usp. In parallel, DUF4118 domain might have undergone domain shuffling events that are independent of the KdpD and Usp domains (Figure 13A).

All the domain architectures of KdpD and DUF4118 proteins were also plotted on the newly published ribosome protein life tree (Hug, Baker et al. 2016). The domain composition and availability of *non-KdpD DUF4118 proteins* are very distinct among the bacterial phyla (Figure 13B). In some phyla, low abundances or even the absence of the *non-KdpD DUF4118 proteins* should prevent interconversion between *kinase* and *non-kinase* KdpD proteins, such as in *Bacteroidetes/Chlorobi* group, *Deinococcus-Thermus*. However, there are also some phyla containing plenty of *non-KdpD DUF4118 protein*s, but almost all of their KdpD proteins are *non-kinase*, such as the *Fibrobacteres/Acidobacteria* group and *Cyanobacteria*.

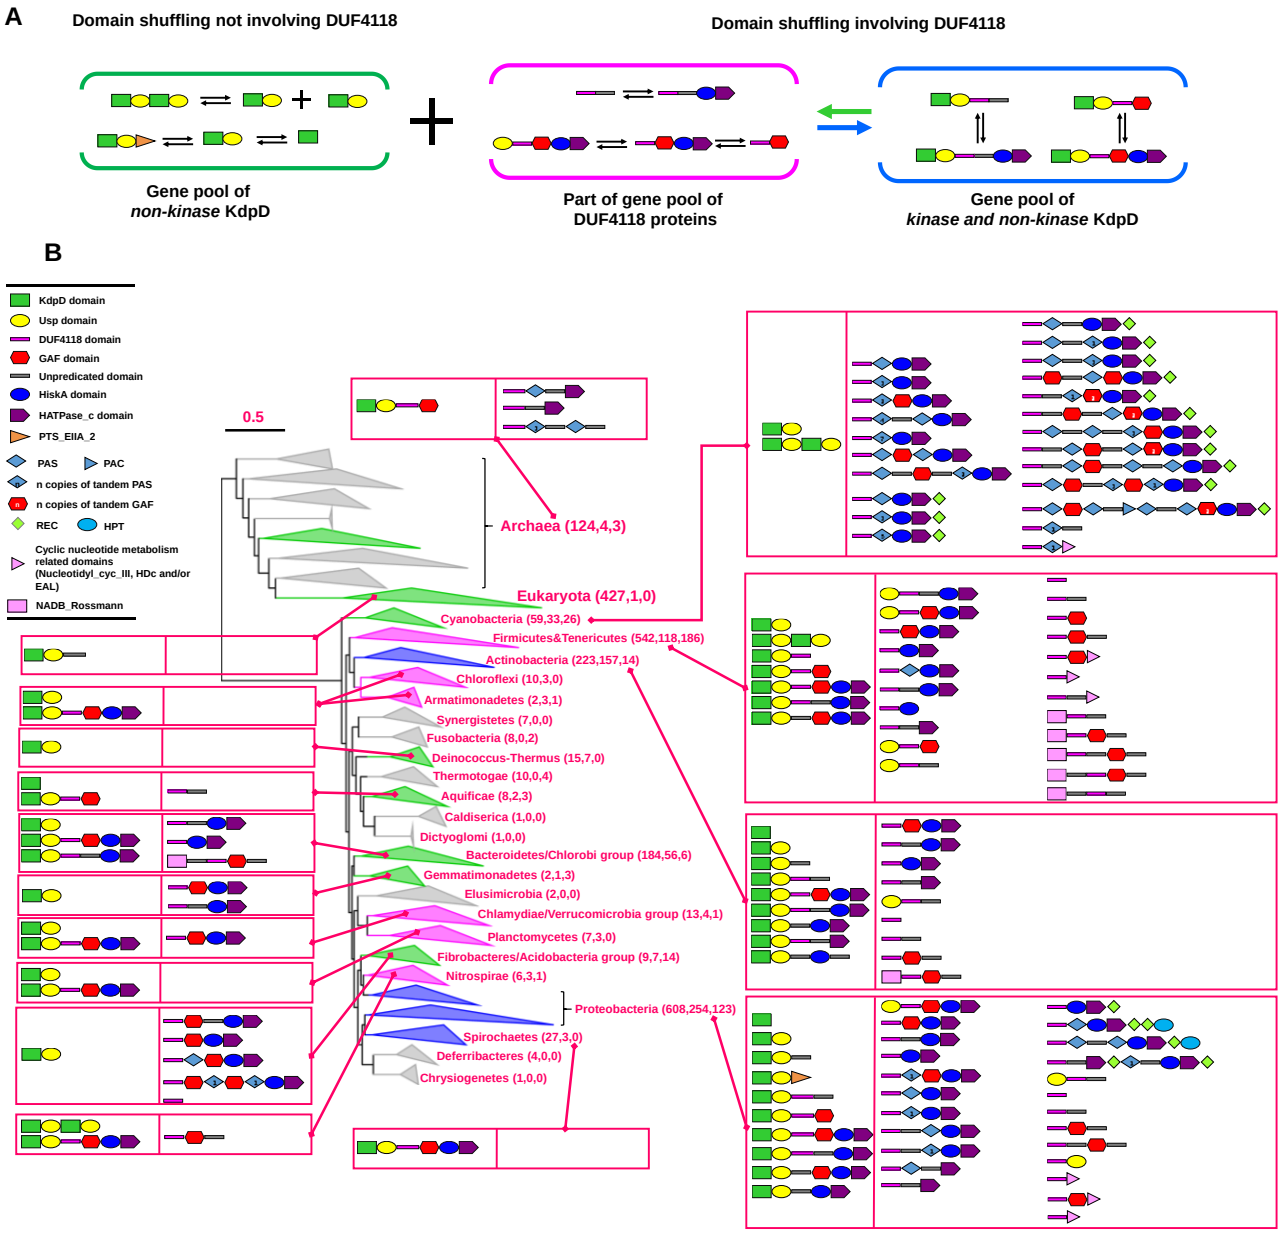

Figure 13: KdpD-Usp and DUF4118 domain recombinatorial routes. (A) Schematic of theoretical domain shuffling between KdpD-Usp and *DUF4118 domain proteins*. There are also domain shuffling events of *non-kinase* KdpD and *non-KdpD DUF4118 proteins* that are independent of each other. **(B)** Domain architectures of KdpD (left columns of the frames) and DUF4118 proteins (right columns of the frames) plotted on the concatenated-ribosomal-protein life tree (unclassified bacteria and the two KdpD proteins belonging to them were not shown; *non-KdpD DUF4118 protein* of the phyla without detected KdpD proteins were exclued). Backbone of the tree was created by modifying the published ribosome protein life tree (Hug, Baker et al. 2016). Leaves of the tree were marked with the taxon names, and in brackets successively, the numbers of reference proteomes and number of detected KdpD proteins and *non-KdpD DUF4118 proteins* in the relevant taxon. Colors of the leaves indicate the proportion of two groups of KdpD (*dysfunctional kinase* was considered as *kinase*); green, ≥90% of the KdpD are *non-kinase*; blue, ≥90% of the KdpD are *kinase*; magenta, both *non-kinase* and *kinase* KdpD accounts for comparable proportions.

In next step it was figured out whether the interconvertsion between *kinase* and *non-kinase* KdpD are purely random events or whether some selection pressure affecting the domain shuffling between Usp and DUF4118 domains.

3.1.5 Global purifying selection / localized positive selection constraints / buttresses interconversion between *kinase* and *non-kinase* KdpD

Nucleotide sequences for the KdpD proteins were retrieved from the protein sequences using tBlast (Altschul, Gish et al. 1990) and Entrez queries. The nucleotide sequences were re-translated into protein sequences and annotated with domains, using CDD v3.14 with a cut-off *E*-value of 0.01 (Marchler-Bauer, Derbyshire et al. 2015).

To infer the phylogeny of the *kdpD* genes, DNA sequences encoding the KdpD domain, the Usp domain and the DUF4118 domain were collected. Only sequences of bacterial accession numbers for which there is exactly one DNA sequence available for the KdpD domain, exactly one DNA sequence for the Usp domain, at most one DNA sequence of the DUF4118 domain were used. The protein sequence alignments obtained from the Pfam profile HMM were mapped to the DNA sequences and concatenated the three domains for each taxon. An alignment of 216 sequences, all of which contained the KdpD domain and the Usp domain, and 141 also contained the DUF4118 domain, were obtained. Program CodonPhyML was used to infer the phylogeny of these sequences (Gil, Zanetti et al. 2013).

KdpD and Usp domains were separately tested for evidence of selection using the program CODEML from the PAML v4.8 package (Yang 2007) with the F3x4 model of codon frequencies and a single value of ω that was inferred simultaneously with the tree and the ratio of transition and transversion rates. A null model that did not allow for variation in ω between the branches of the phylogeny was used for the first CODEML run. Then, a parsimonious set of branches in the *kdpD* gene phylogeny that separate the *kinase* and *dysfunctional kinase kdpD* genes from the *non-kinase kdpD* genes was identified [*dysfunctional kinase* was considered as *kinase*

herein, because *dysfunctional kinase* is a minority which has similar domain architecture to *kinase*]. It was tested whether ω was increased on these branches on the KdpD and Usp domains, which will indicate positive selection on these candidate branches associated with the conversion from *kinase* to *non-kinase* (or vice versa). For this, CODEML was applied to fit a model in which two different ω values were allowed, one for the candidate branches and one for all other branches. In addition a model with seven ω values, one for each candidate branch and one for all other branches, was fitted. These models were fitted separately to the KdpD domain sequence alignment and to the Usp domain sequence alignment. In addition to the differences between synonymous and non-synonymous, mutations differences in the rates of transitions and transversions were taken into consideration. The mutation rates were estimated within the CODEML analyses.

With the null model, in which only one value of ω was allowed throughout the tree, the average ratios of non-synonymous to synonymous mutation rates (ω) for the entire phylogeny were 0.099 for the KdpD domain and 0.075 for the Usp domain. These values indicate that these domains are under strong purifying selection.

When a different ω value was allowed on the six candidate branches that separate *kinases* from *non-kinases* (Figure 14, marked with rectangle, circle, or star), the estimated values on the candidate branches were ω=0.295 for the KdpD domain and ω=0.128 on the Usp domain, whereas the ω values on the other branches remained similar to the values inferred with the null model (0.098 for the KdpD domain and 0.074 for the Usp domain). This model fitted significantly better for the KdpD domain but not for the Usp domain (p values $<10^{-9}$ for the KdpD domain, 0.17 for the Usp domain; likelihood-ratio test, with χ^2 approximation, df=1).

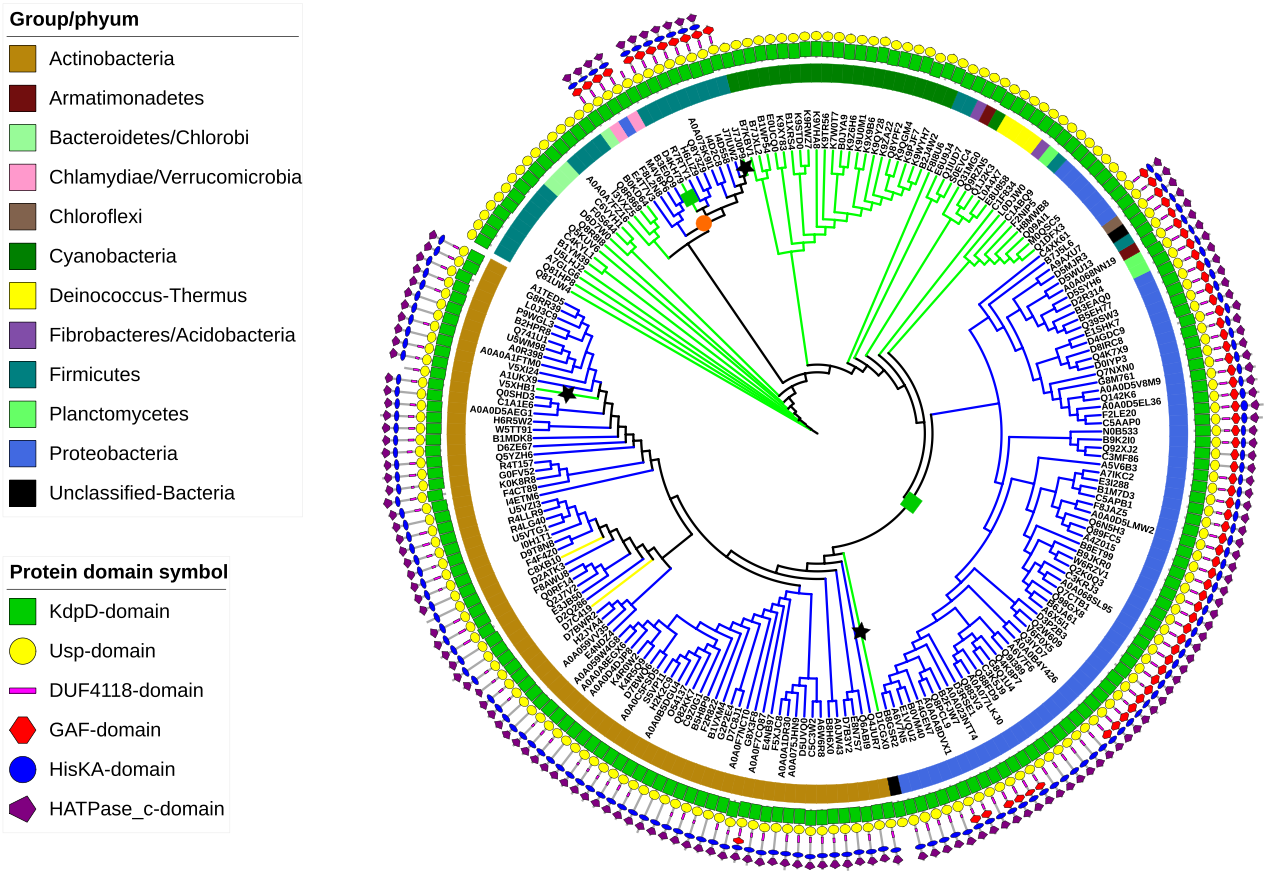

Figure 14: Selection pressure analysis on KdpD and Usp domains. Backbone of the tree was constructed with CodonPhyML (see the chapter of Materials and Methods). Branch color demonstrates the type of analyzed KdpD protein (blue, *kinase* KdpD; yellow, *dysfunctional kinase* KdpD; green, *non-kinase* KdpD). Colored ring indicates the bacterial taxa (see Data set-sheet 7 for species names). Domain architectures of KdpD were predicted with CDD v3.14. Branches with positive selection on KdpD domain were marked with green rectangles, and those with positive selection on both KdpD and Usp domains were marked with orange circles. Black stars indicate the candidate branches which may support the interconversion between *kinase* and *non-kinase* but without detected positive selection on either KdpD domain or Usp domain.

For the KdpD domain the model in which each of the six candidate branches was allowed to have its own value of ω (in addition to one ω for all non-candidate branches) fitted significantly better than the model with only two ω values (p value < 10^{-12}, df=5). For the Usp domain this model was compared to the model with only one ω value for all branches as this model was not rejected in the comparison to the model with two ω values. It was found that the model with different ω values for the candidate branches fits significantly better (p value 0.035, df=5). With

this model, *ω* was estimated to be greater than 1 (indicating positive selection) for both domains on the branch that is marked with an orange circle in Figure 14 (Table 5). On the two branches that are marked with a green rectangle only the *ω* values for the KdpD were estimated to be greater than 1 (Table 5). One of them leads to a single taxon (D4KH79, *Megamonas hypermegale*). On this branch the value for the Usp domain (0.444) was still substantially higher than the value for the non-candidate branches (0.075 with this model) (Table 5).

Table 5: Selection pressure analysis on KdpD and Usp domains

Branch	KdpD domain			Usp domain		
	N•dN[a]	S•dS[b]	*ω* (dN/dS)	N•dN[a]	S•dS[b]	*ω* (dN/dS)
Internal A	24.202	0.011	633.058	0	0	0.0001
Internal B	52.998	0.011	965.763	14.776	0.005	999
V5XHB1	48.568	62.44	0.218	3.109	1449.532	0.001
D1CGX0	90.695	916.39	0.028	28.579	1423.992	0.008
D4KH79	116.497	31.627	1.031	20.262	17.188	0.444
J7J0P9	19.772	77.857	0.071	2.692	15.463	0.066
All other	8068.716	22842.98	0.099	1756.113	8795.949	0.075

Numbers of non-synonymous ([a]) and synonymous ([b]) mutation and *ω* values as estimated by CodeML with a model that allowed for different dN and dS values on six candidate branches. The internal branch A was marked with a green rectangle in Figure 14. Internal branch B was marked with an orange circle in Figure 14. For branches that lead to only one taxon the identifier of the taxon was given (See also Data set-sheet 7). Note that large values given by CodeML should be taken with caution. E.g., 999.000 was the maximum value given by CodeML, just indicating that there is evidence for non-synonymous mutations but not for synonymous mutations.

3.2 Alternative HK^{K+}/RR^{K+} regulate Kdp system

3.2.1 Prediction of new alternative HK^{K+}/RR^{K+}

The fact that *non-kinase* KdpD proteins lack the output domain of HisKA and HATPase_c raises the question of how the expression of *kdp* operons might be regulated in these species. In light of earlier work on the Kdp system in *Cyanobacteria* (Ballal and Apte 2008, Nanatani, Shijuku et al. 2015), the genomic neighborhoods (within ±15 kbp of the *kdpD* start codon and

stop codon) of all *non-kinase kdpD* genes were checked (genomic neighborhoods of some of the *non-kinase kdpD* genes were depicted in Figure A3). Genes for three major types of HK^{K+} were identified in these regions: **(i)** DUF4118-GAF(X)-HK^{K+} (mainly found in *Firmicutes* and the *Fibrobacteres/Acidobacteria* group; X stands for an unpredicted domain); **(ii)** 4TM(2TM)-HK^{K+} (found in *Cyanobacteria* and *Deinococcus-Thermus*); and **(iii)** 2TM-HAMP-PAS(X)-HK^{K+} (X stands for an unpredicted domain), which might phosphorylate σ^{70} family sigma factors related RR (found in some *Firmicutes*) or σ^{54}-dependent transcriptional activator (found in some deltaproteobacterial species and in the *Bacteroidetes/Chlorobi* group) (Figure 15, Data set-sheet 8).

In agreement with this idea, it has been experimentally proven that a HK which has the domain architecture of 4TM(2TM)-HK^{K+} can mediate the regulation of *kdp* genes in cyanobacteria (Ballal and Apte 2008, Nanatani, Shijuku et al. 2015). Moreover, the C-terminal portion of *E. coli* KdpD, which is homologous to DUF4118-GAF(X)-HK^{K+}, is able to sense extracellular K^+ (Rothenbucher, Facey et al. 2006, Schramke, Tostevin et al. 2016).

Sigma factors are essential for bacterial RNA polymerase (RNAP) to recognize promoters (Gruber and Gross 2003, Kazmierczak, Wiedmann et al. 2005, Filloux 2012). There are two families of sigma factors. The σ^{70} family includes housekeeping sigma factors as well various alternative sigma factors. The σ^{54} family differs in sequence and structure from all other sigma factors and contains exclusively the σ^{54} (Lonetto, Gribskov et al. 1992, Gruber and Gross 2003). As assumed above, HK^{K+} of the *non-kinase* KdpD might phosphorylate a σ^{54}-dependent RR^{K+} (σ^{54}-dependent transcriptional activator) in some species of the *Deltaproteobacteria* and the *Bacteroidetes/Chlorobi* group (Figure 15, Data set-sheet 8).

In agreement with this assumption, DNA-affinity-purified-chip assay has shown that two σ^{54}-dependent transcriptional activators DVU0596 and DVU3305 bind to the upstream of *kdp* operon in *Desulfovibrio vulgaris* Hildenborough, a typical deltaproteobacteria strain (Rajeev,

Luning et al. 2011). Moroever, as will be proved, the RR^{K+} of *Bacteroides fragilis* KdpD, a σ^{54}-dependent transcriptional activator was also found affecting the expression of *B. fragilis kdp* operon (See section 3.2.2, Figure 17 for details). Tighter regulation of σ^{54} factor dependent *kdp* operons could be expected, since ATP hydrolysis by these transcriptional activators is required to overcome the kinetic barrier and form the open complex at the promoter (Rombel, North et al. 1998, Buck, Gallegos et al. 2000, Studholme and Dixon 2003, Bush and Dixon 2012).

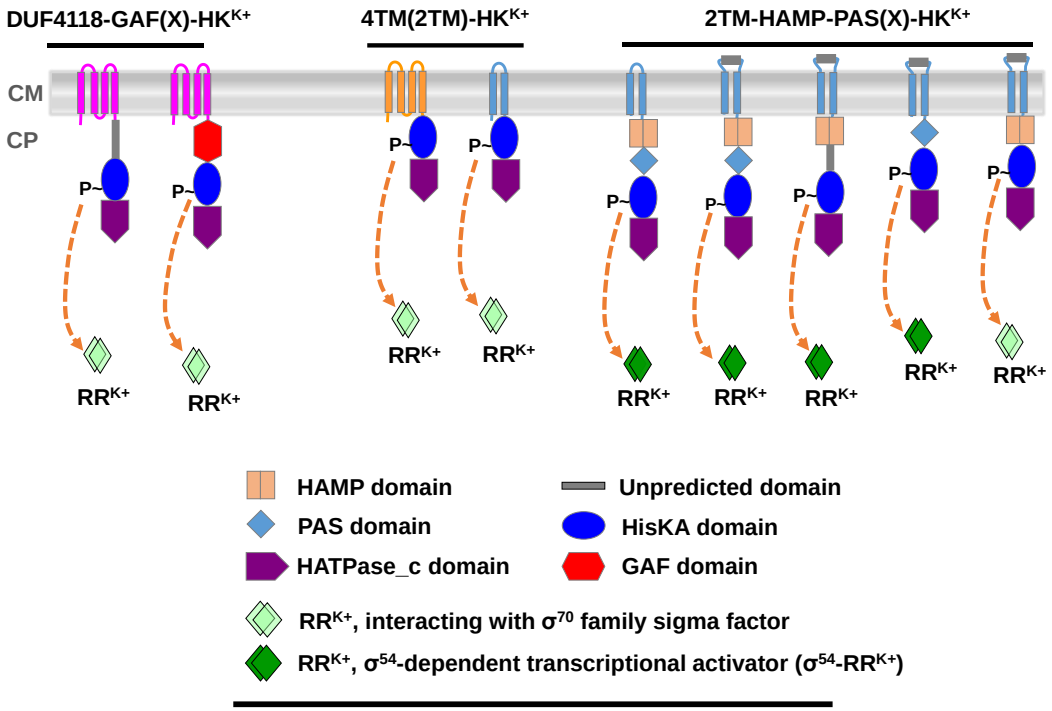

Figure 15: Alternative HK^{K+}/RR^{K+} pairs found in the genomic neighborhoods of *kdp* operons. Representative domain architectures of HK^{K+} and RR^{K+} are shown. CM, cytoplasmic membrane; CP, cytoplasm; X, unpredicted domain; DUF4118 (four-helix transmembrane domain with K^+ binding site, magnate); 4TM, four-helix transmembrane domain (orange); 2TM, two-helix transmembrane domain (pale blue).

3.2.2 Characterization of the Kdp system of *B. fragilis*

As described above, some Kdp systems equipped with *non-kinase* KdpD may recruit putative alternative HK^{K+}/RR^{K+} to transcriptionally regulate the *kdp* operons. It is aimed subsequently to verify the roles of 2TM-HAMP-PAS(X)-HK^{K+} and σ^{54}-dependent transcriptional activator, σ^{54}-

RR^{K+} (Figure 15), which is especially interesting and was mainly found in some *Delta-proteobacteria* and *Bacteroidetes/Chlorobi* species. The *B. fragilis* was chosen because **(i)** *B. fragilis* is an important intestinal commensal bacteria as well as an opportunistic pathogen highly related to human health concerns, while Kdp system is believed to participating the pathogenicity is some bacteria (Freeman, Dorus et al. 2013); **(ii)** Human colon is generally a K^+ rich environment. It is aimed to disclose the role of Kdp system encoded in the *B. fragilis* genome.

3.2.2.1 Prediction of the components of *B. fragilis* Kdp system

The Kdp system of *B. fragilis* is predicted to have *kdpFABCO* as the structural genes and hk^{K+}/rr^{K+} as the core regulating components (Figure 16A). KdpF is a short peptide which was annotated in the genome of *E. coli* but not in the genome *B. fragilis*. But a typical SD sequence was found upstream of *kdpA*, followed by a putative ORF starting with “ATG” and ending with “TAA” codons (Figure 16A). The amino acid sequence translated from this short ORF shows high similarity to the *E. coli* KdpF. They both should have the structure of hydrophobic α-helix (Figure 16D).These findings suggest KdpF should be also encoded in the *B. fragilis kdp* operon.

As described in 3.2.1, the RR^{K+} was predicted to be a σ^{54}-dependent transcriptional activator and the HK^{K+} was predicted to be 2TM-HAMP-PAS-HK^{K+} (Figure 16C). Unlike the *E. coli* or cyanobacterial Kdp system, the genes encoding the HK^{K+} and RR^{K+} do not share the same operon (Figure 16 indicated with blue and green arrows). Moreover, the putative σ^{54} recognition motif was found in the promoter of *B. fragilis kdp*. It is about 170 bp upstream of the start codon of the predicted *kdpF.* In the Dataset-sheet 9, 23 more *kdp* operons were found to have similar motifs in their promoters. All these *kdp* operons were equipped with *non-kinase* KdpD and were found in sixteen *Bacteroidetes* and seven *Deltaproteobacteria.* The σ^{54} recognition motif is quite different from that of σ^{70}, the house keeping sigma factor (Francke, Groot Kormelink et al. 2011). Moreover, the transcriptional initiation at of σ^{54} dependent promoter strictly requires

the hydrolysis of ATP to form initiation complexes (Rombel, North et al. 1998, Buck, Gallegos et al. 2000, Studholme and Dixon 2003, Bush and Dixon 2012). Such kind of transcription initiation mechanism leads to tighter regulation of the Kdp system of *B. fragilis*, which principally has very low probability to face K^+ limitation.

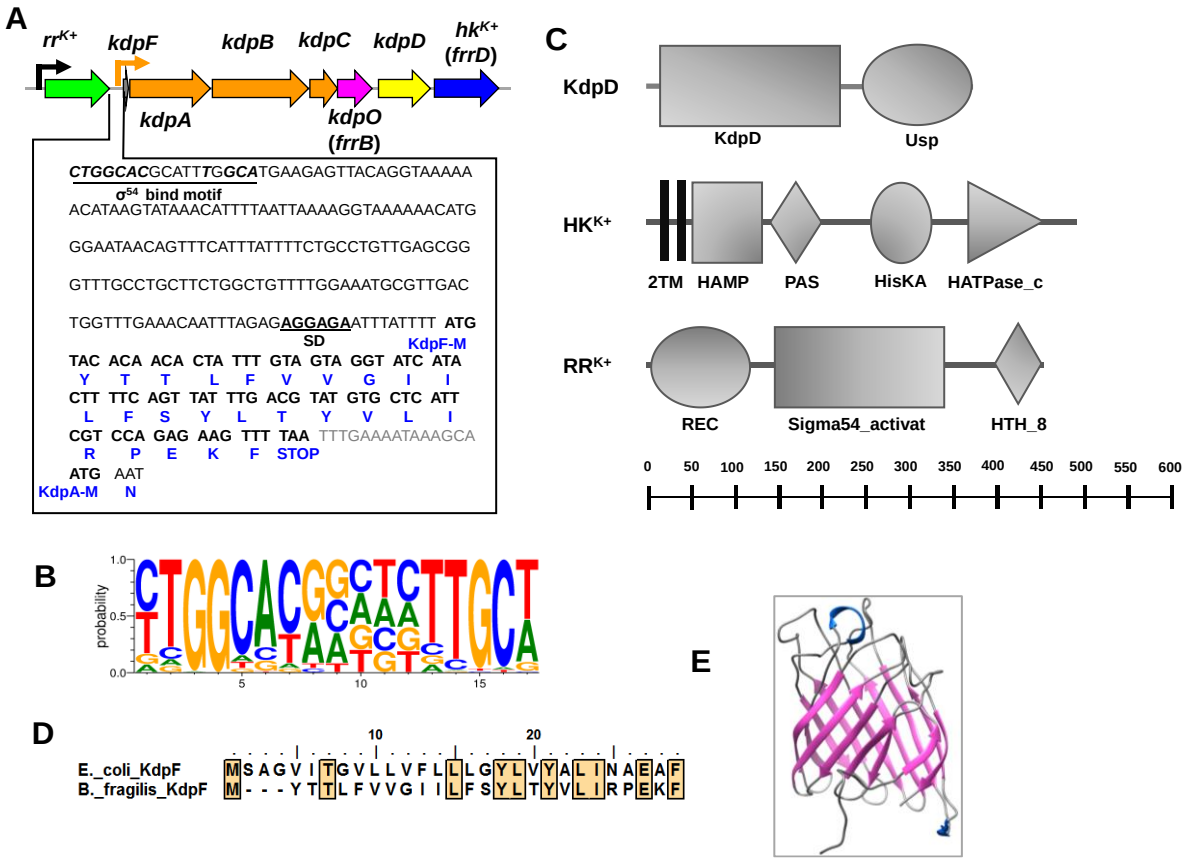

Figure 16: Predicted elements of Kdp system in *B. fragilis* (A) Predicted genes that encode the Kdp system in *B. fragilis*. Amino acid sequence of the predicted KdpF is marked with blue color. Underline sequences designate the putative σ^{54} regonization motif (italic) and the SD sequence (bold) of the *kdpF* gene, respectively. **(B)** DNA sequence logo constructed from known σ^{54} recognition motif (Barrios, Valderrama et al. 1999). **(C)** Predicted domain architectures of KdpD, RR^{K+} and HK^{K+}. **(D)** Sequence comparision between the KdpF of *E. coli* MG1655 and the predicted KdpF of *B. fragilis.* Identical amino acid are highlighted with backgroup color. **(E)** Three dimensional structure model of KdpO (FrrD).

In addition, between *kdpC* and *kdpD* there is an ORP (*frrB*) encoding a putative outer membrane porin, which is composed of 14 predicted β-strands (Figure 16E). In this thesis, this

protein was renamed as KdpO. KdpO may increase the permeability of the K^+ from extracellular environment to the periplasm to speed up the uptake K^+ by the KdpFABC located in the inner membrane.

3.2.2.2 Test the stimuli of Kdp system in *B. fragilis* reporter

As described above, the signal molecules of the *B. fragilis* Kdp system is rather mysterious, since this bacterium habits the K^+ rich mammal colon. To test the stimulus of *B. fragilis* Kdp system, a *B. fragilis* reporter strain *B. fragilis* Wlu was constructed (Figure 17A), in which the luciferase gene *Nluc* is under the control of *B. fragilis kdp* promoter $P_{kdp\ B.\ fragilis}$. Luminescence intensity per OD_{600} is used to demonstrate *kdp* promoter activities. The reporter was tested to three kinds of possible signals: K^+ concentration, osmostress (by sucrose) or salt stress (by NaCl). Briefly, the *B. fragilis* Wlu reporter strain was cultivated in AMMgluc medium with different concentrations of K^+ or AMMgluc medium added with indicated amount of sucrose or NaCl (K^+ was set to 10 mM) for 9 hours. Luminescence intensity per OD_{600} was measured as an indication of the *kdp* operon expression.

Interestingly, Kdp system of *B. fragilis* is indeed reponsing to K^+ limitation. The expression of *kdp* operon could be strongly induced by low K^+ and was switched off when K^+ is higher than 5 mM (Figure 17B). Conversely, the expression of *kdp* operon was slightly increased by osmostress or salt stress (about one fold increase, Figures 17C and 17D). This result suggests that the expression of *B. fragilis kdp* operon shows unspecifical responses to osmostress or salt stress. High concentration of sucrose (>=0.6 M) and NaCl (>=0.3 M) strongly inhibit the growth of *B. fragilis* reporter strain. Therefore, the relevant luminescence intensities could not be measured (Figures 17C and 17D).

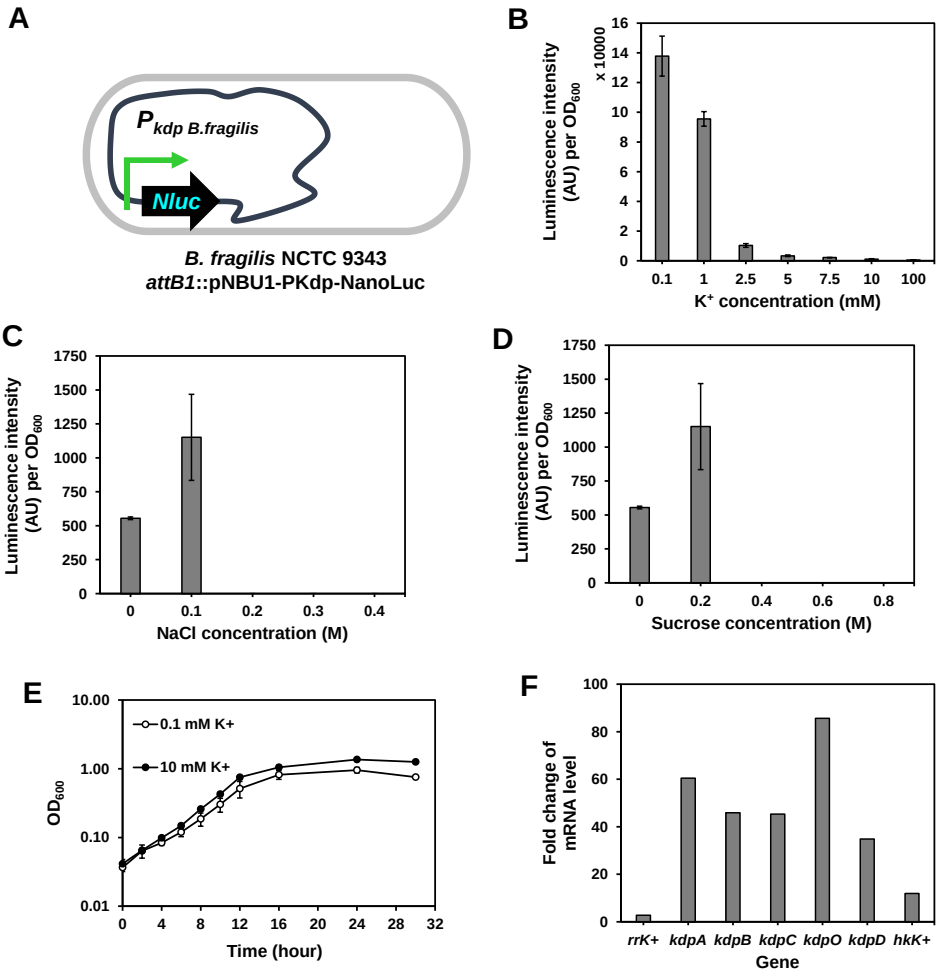

Figure 17: Test the stimuli of Kdp system in *B. fragilis*. (A) Construction of the *B. fragilis* Wlu reporter strain. In the reporter luciferase gene was located under the control of $P_{kdp\ B.\ fragilis}$ on the backbone of shuttle vector pNBU1, which was integrated into the *attB1* site on chromosome of *B. fragilis* NCTC 9343. **(B)-(D)** Test the response of Kdp system to K^+ concentration, salt stress and sucrose osmostress, respectively. High concentration of sucrose (>=0.6 M) and NaCl (>=0.3 M) stongly inhibit the growth of *B. fragilis* reporter strain. **(E)** Impact of K^+ on the growth of *B. fragilis* wild type strain. **(F)** Change of mRNA level of the predicted *kdp* genes in response to K^+ limitation. Cells were cultivated in AMMgluc medium with indicated K^+ concentrations for 14 hours and were collected for total RNA isolation. The expression of gene *recA* was selected as the reference for qRT-PCR.

To further confirm the stimulus of *B. fragilis* Kdp system is K^+ limitation, qRT-PCR was used to measure the transcriptional alternations of the *kdpA*, *kdpB*, *kdpC*, *kdpO*, *kdpD*, rr^{K+} and hk^{K+} in response to K^+ concentrations. In agreement with the luciferase reporter assay, expression levels of *kdpA*, *kdpB*, *kdpC*, *kdpO*, *kdpD* were strongly stimulated by 30 to 90 folds, when cells

were grown under K^+ limitation (0.1 mM). Additionally, this finding also indicates that these five genes sharing the same operon. The transcription of *hk*$^{K+}$ was also stimulated by low K^+ but less significantly (10 folds increase) (Figure 17E). To verify whether *hk*$^{K+}$ is also included into the *kdp* operon, further experiment, *e.g.* Northern blot, is required to measure the structure of the *B. fragilis kdp* operon composition. Growth of the *B. fragilis* wild type strain was also tested the in minimal medium with 0.1 mM and 10 mM K^+. Low K^+ causes dimished biomass formation (Figure 17F) of this bacterium. This result indicates that the *B. fragilis* species requires proper K^+ concentration (~10 mM) for normal growth.

3.2.2.3 Test the role of the putative Kdp-regulating HK^{K+}/RR^{K+} in *E. coli* reporter

In order to confirm the regulation role of the predicted KdpD, HK^{K+}/RR^{K+} in Figure 15, these three genes were expressed under control of arabinose promoter P_{BAD} individually or in combination in the reporter strain *E. coli* YW2, in which the native promoter of chromosomal *lacZ* gene has been replace by the $P_{kdp\ B.\ fragilis}$ (Figure 18A). β-Galactosidase per OD_{600} is used to demonstrate the activity of the *kdp* promoter in the reporter strain. *E. coli* YW2 transformed with the listed genes was cultivated in minimal medium with various concentrations of K^+ (see 2.2.6). Increase of β-galactosidase was observed, when *rr*$^{K+}$ and *rr*$^{K+}$ and *hk*$^{K+}$ were expressed from the arabinose promorter leakage. However such kind of increase is not in response to K^+ (Figure 18B). Considering *kdpO* gene was not found in the *E. coli kdp* operon, in order to check its potential effect on the K^+ sensing capability of HK^{K+}/RR^{K+}, this gene was also expressed on the pBAD33 vector from P_{BAD} in combination with *hk*$^{K+}$/*rr*$^{K+}$ in the *E. coli* YW2. However, KdpO does not endow the K^+ response capability of HK^{K+}/RR^{K+} in *E. coli* reporter. The deregulation of the HK^{K+}/RR^{K+} in *E. coli* may due to two reasons. **(i)** Essential co-sensor of the HK^{K+}/RR^{K+} is not available in *E. coli*; **(ii)** *The B. fragilis kdp* operon includes the *hk*$^{K+}$. This would mean a positive feedback amplification of *kdp* operon. In responding to low K^+, *hk*$^{K+}$ needs to increase the expression of itself to amplify the low K^+ signal to increase efficently the expression of

kdpFABC. Such kind of positive feedback amplification may be destroyed in the *E. coli* reporter because the hk^{K+} expression is constantly from P_{BAD} (Figure 18D).

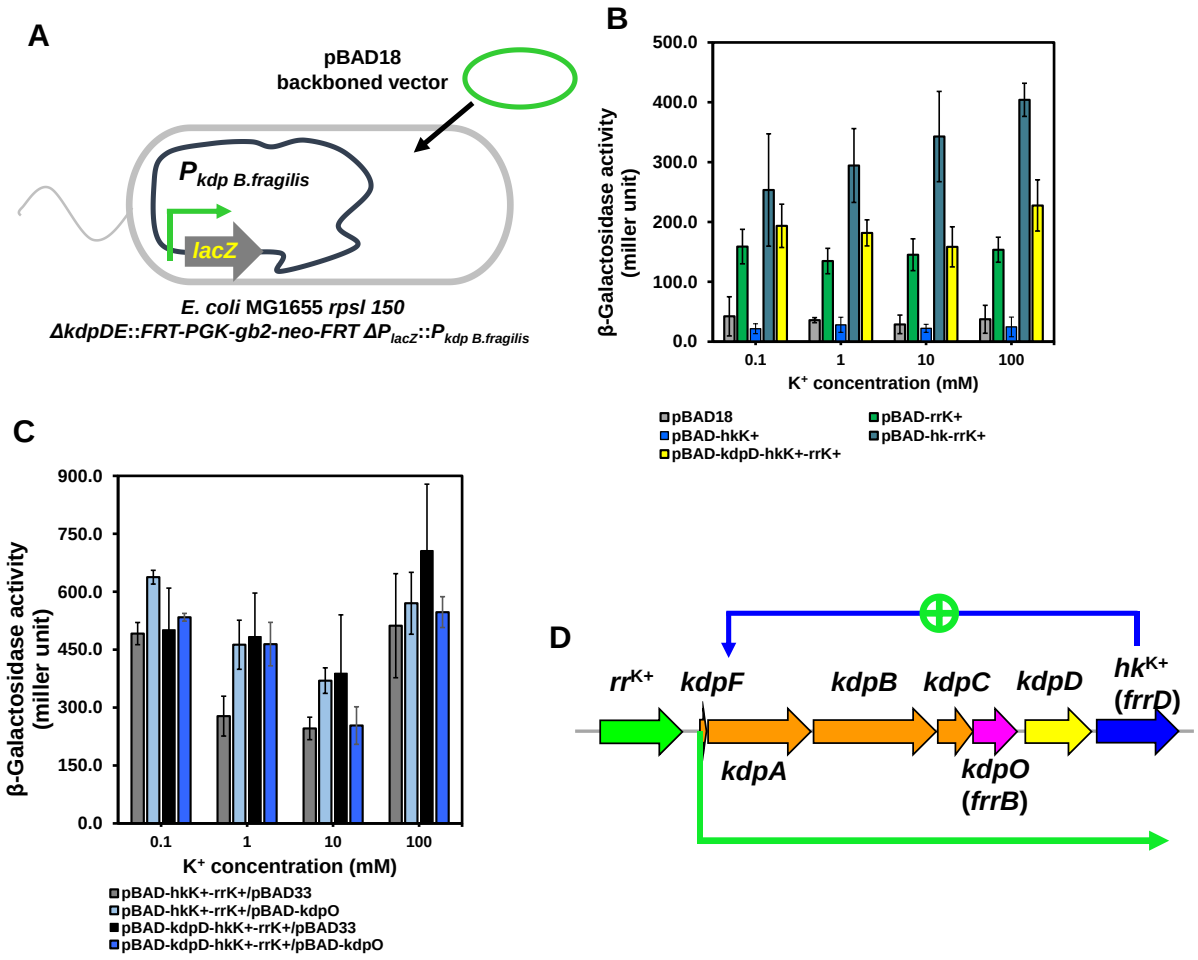

Figure 18: Test the role of the putative Kdp-regulating H^{K+}/RR^{K+} in *E. coli* reporter. (A) Construction of the *E. coli* reporter strain. In the *E. coli* reporter the native *kdpDE* system was removed and the chromosomal *lacZ* was under the control of $P_{kdp\ B.\ fragilis}$. **(B)** rr^{K+}, hk^{K+}, rr^{K+}& hk^{K+}, rr^{K+}& hk^{K+}& *kdpD* were expressed individually or in combination from the P_{BAD} promoter leakage. **(C)** Gene *kdpO* was expressed on pBAD33 vector in combination with hk^{K+}/rr^{K+} or with $kdpD/hk^{K+}/rr^{K+}$. KdpO does not endow the HK^{K+}/RR^{K+} K^+ response capability in *E. coli* reporter. **(D)** Suppose hk^{K+} is involved in the *kdp* operon, there would be a positive feedback loop. This loop may be interrupted when the related genes were expressed on the vector while the *kdp* promoter was integrated into *E. coli* genome.

3.3 Structural analysis of KdpD proteins

3.3.1 Purification of "full-length" *E. coli* KdpD proteins and crystallization trials

It is conceivable that the wild type *kinase* KdpD should have flexible conformational transition, because its kinase and phosphatase activities are altered instantly by the change of K^+ concentrations. This accordingly raises the obstacle for crystallization setups. Therefore, a variant with constant kinase activity (indicating more rigid in conformational transition), KdpD-R511Q (Jung and Altendorf 1998), was chosen as the candidate for initial crystallization setups. The KdpD-R511Q-6His was successfully purified from membrane vesicles as described in the chapter of Materials and Methods, with more than 90% purity (Figure 19). The sample was subsequently sent to the collaborator, Prof. Dr. Jörg Stetefeld, for crystallization. Unfortunately, after several rounds of trials, the protein precipitated and no crystals were obtained.

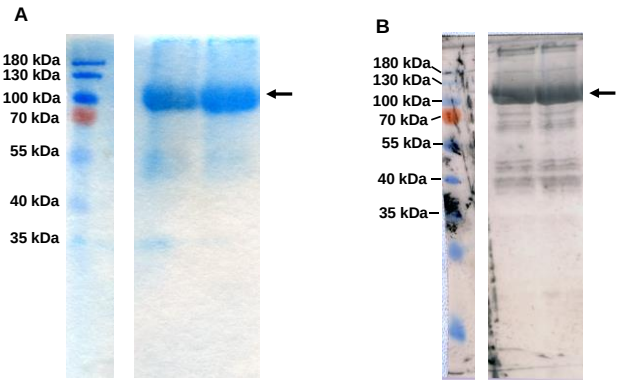

Figure 19: Purified KdpD-R511Q used for initial crystallization setups. **(A)** Coomassie Brilliant Blue G-250 staining and (**B)** Western blot with KdpD polyclonal antiserum as the first antibody. Arrow indicates the purified KdpD-R511Q-6His.

As shown in Figures 2 and 20A, *kinase* KdpD protein integrated into lipid bilayers are very asymmetric. KdpD, Usp, GAF, HiskA and HATPase_C domains are located one side of the membrane (cytoplasm), while there are just two small loops of the DUF4118 domain on the other side (Figures 2 and 20A). The first periplasmic loop is very short, with four amino acids,

while the second periplasmic loop is longer and essential for K^+ sensing (Schramke, Tostevin et al. 2016). Such kind of asymmetry may hinder the formation of crystal lattice.

To increase the molecular symmetry and therefore support the downstream crystallization experiments, WrbA, a soluble flavodoxin protein, was inserted into the first periplasmic of *E. coli* KdpD. WrbA is a NAD(P)H:quinone oxidoreductase with 198 amino acids (20.6 kDa). Each of the WrbA monomer binds FMN as the cofactor and the protein has been crystallized successfully as yellow colored bipyramid (Patridge and Ferry 2006, Kishko, Carey et al. 2013). To protect the folding independence of the KdpD and WrbA, flexible glycine and serine linkers were inserted between the WrbA and KdpD periplasmic loop.

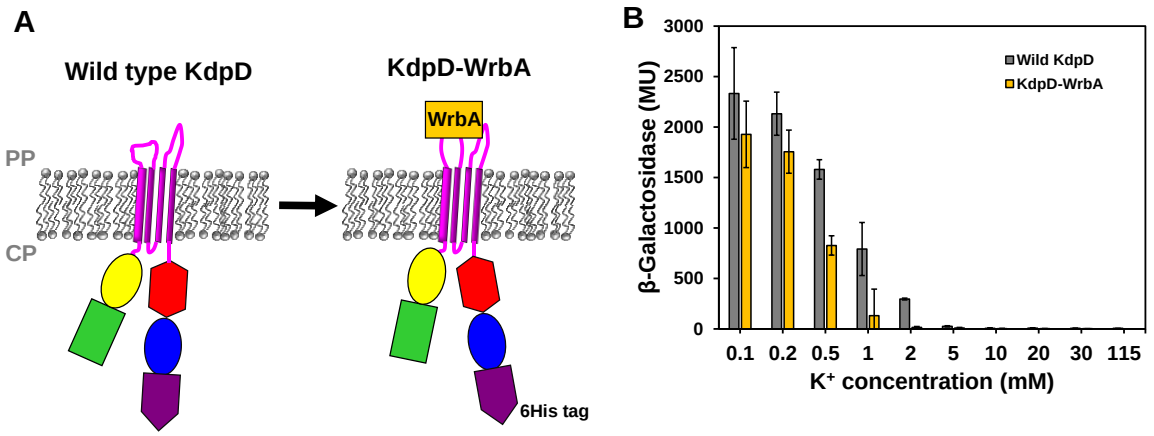

Figure 20: Construction and functional assay of KdpD-WrbA. **(A)** Schematic of the wild type KdpD and the KdpD-WrbA hybrid protein in to the lipid bilayers. Six histidine tag was attached to the C-terminal end of HisKA_c domain for subsequent protein affinity chromatography. PP, periplasm; CP, cytoplasm. **(B)** Test the response of the KdpD-WrbA to K^+ concentrations in comparison to the wild type KdpD. Standard deviations were calculated based on three parallel measurement.

The functionality of this hybrid protein was firstly determined to make sure the overall structure of the protein was not destroyed by the insertion of the WrbA into the K^+-sensing domain, DUF4118. β-Galactosidase assays suggest the KdpD-WrbA protein works properly. This

hybrid protein responses to the decreased K^+ concentration like the wild type *E. coli* KdpD (Figure 20B).

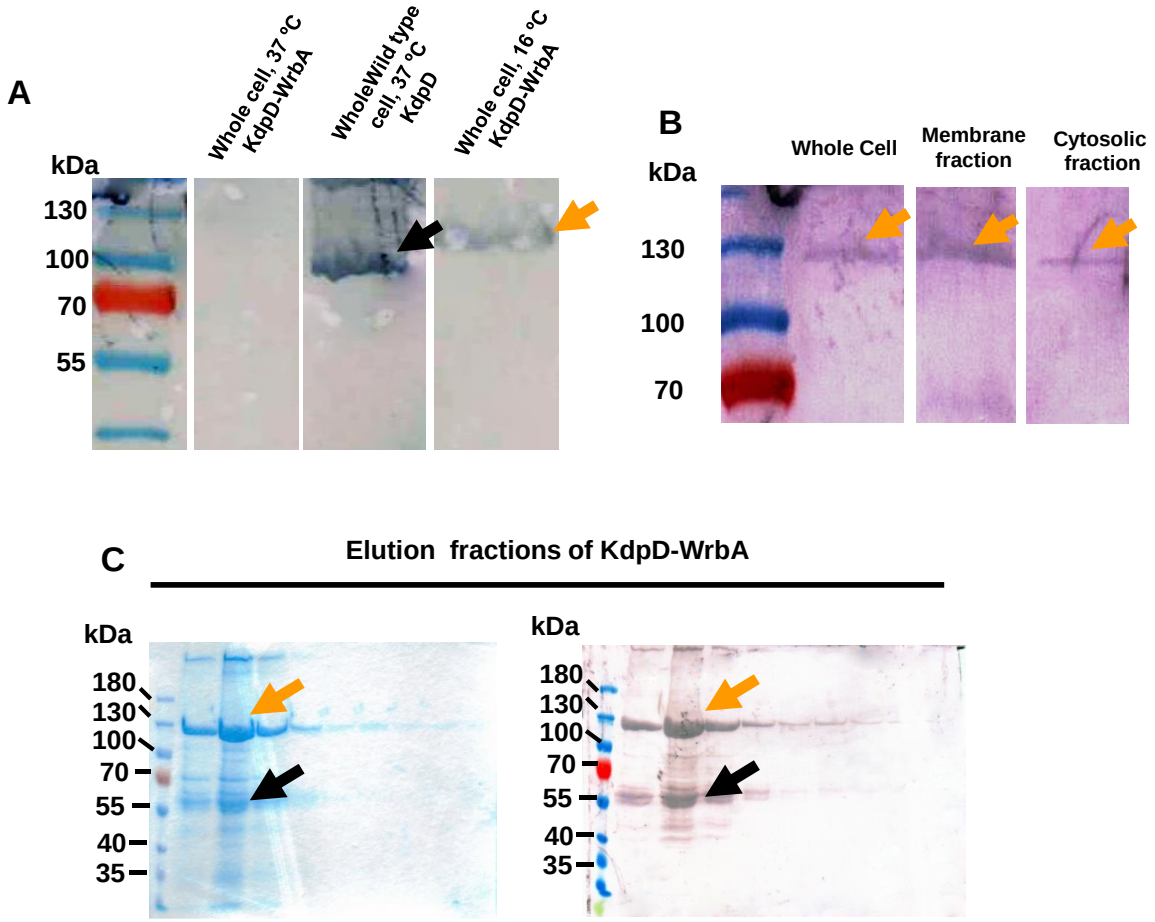

Figure 21: Localization analysis and purification of KdpD-WrbA hybrid. **(A)** KdpD-WrbA production was carried out with *E. coli* BL21 (DE3) induced with 0.3% (w/v) L-arabinose at 37°C for 3 hours or at 16°C for 15 hours. Equal volume (25 µL) of the cultures were loaded on SDS-gel. The wild type KdpD (black arrow) can be accumulated efficiently in the cells at 37 ºC, while KdpD-WrbA hybrid (yellow arrow) must be produced at lower temperature of 16 ºC. **(B)** KdpD-WrbA is mainly located into the cytoplasmic membrane. Cell were lysed with sonication and cytoplasmic membrane and cytoplasm fractions were separated with ultracentrifugation as described. Membrane fraction was resupended to the same volume of cytoplasm fraction, and equal volume (25 µL) of membrane and cytoplasm fraction were loaded on the SDS-gel. **(C)** Evaluation of the KdpD-WrbA elution fraction from affinity chromatograph. Left, Coomassie Brilliant Blue G-250 stained; right, Western blot (KdpD polyclonal antiserum as the first antibody). Large proportions of KdpD-WrbA were truncated (black arrow). All Western blots were performed with KdpD polyclonal antiserum as the first antibody.

However, when cultivation of the *E. coli* B21(DE3) carrying the pBAD24-KdpD-WrbA-6His vector was carried out at 37 °C with the induction of 0.3% (w/v) L-arabinose, the production of the hybrid protein could be hardly detected by Western blot. When the cultivation was performed at low temperature (16 ºC), production KdpD-WrbA hybrid was detected, but to a level which is much lower than that of the wild type KdpD (Figure 21A). Moreover, not all of the KdpD-WrbA proteins were incorporated successfully into the cytoplasmic membrane. Hybrid protein was also detected in the cytoplasmic fraction (Figure 21B). KdpD-WrbA proteins could be purified with the same protocol adopted for purification of KdpD-R511Q. However, compared to KdpD-R511Q, KdpD-WrbA is quite unstable. About 30% of the proteins were degradated or truncated by premature translation-termination (Figure 21C). Considering the very high requirements to purity and stability in crystallization setups, KdpD-WrbA was not used.

3.3.2 In search of soluble KdpD for crystallization

Since all the trials on crystallization of *kinase* KdpD were not fruitful thus for, any soluble and stable fragment of the *non-kinase* part of KdpD would be embraced as alternative candidate. *Non-kinase* KdpD with the domain architecture of KdpD-Usp was supposed to be located in the cytoplasm (see section 1.3.2). However, *E. coli kinase* KdpD by artificial truncation (*E. coli* KdpD 1-395 amino acids) was found to be attached to the membrane (Heermann, Altendorf et al. 2000). Similarly, native occurring *non-kinase* KdpD of *D. radiodurans* (see section 3.1.2, *Deinococcus-Thermus* has only *non-kinase* KdpD) also has poor solubility and a high tendency to bind to the cytoplasmic membrane (Figure 22A). It is not wise to apply these *non-kinase* KdpD straightly to crystallization setups, considering their hydrophobic features. In order to find a readily soluble and stable fragments of KdpD proteins, the *E. coli* KdpD 1-395 was purified and treated with limited proteolysis. Stable fragments were anticipated to gain better solubility. When *E. coli* KdpD 1-395 were digested respectively with proteinase K, trypsin and subtilisin, a stable fragment was identified with molecular mass of about 35 kDa (Figure 22B).

This band was extracted and tested with mass spectrometry. The composition of this band was found to be KdpD 38-380. The coding region of KdpD 38-380 was subsequently amplified as an ORF and overexpressed in *E. coli* BL21(DE3). Unfortunately, this protein variant still show affinity to the cytoplasmic membrane (Figure 22C), and therefore not suitable for crystallization setups.

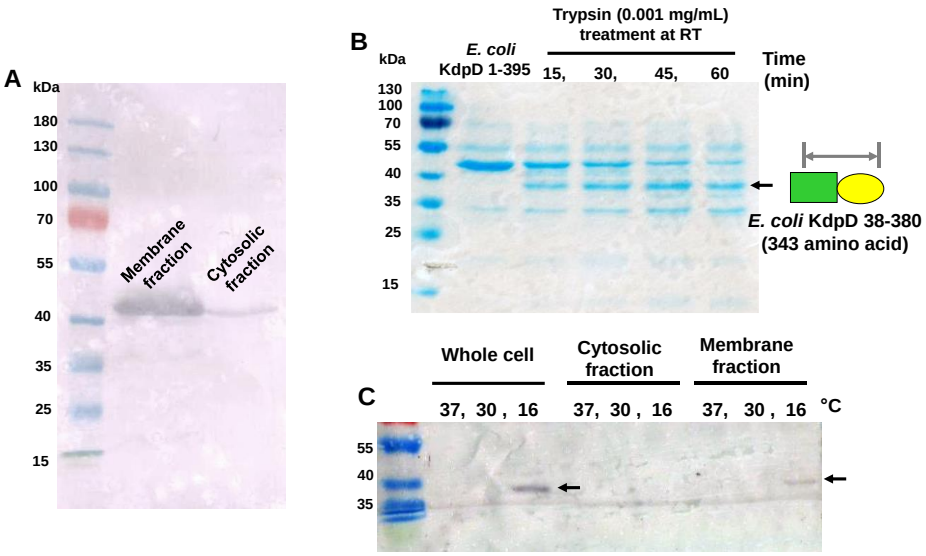

Figure 22: In search of soluble KdpD fragments. (A) *E. coli* BL21(DE3) cells producing the native *non-kinase* KdpD of *D. radiodurans* protein were lysed and cytoplasmic membrane and cytoplasm were separated via ultracentrifugation. Cytoplasmic membrane was resuspended with lysis buffer to the same volume of the cytoplasm fraction, and 25 µL of these two fractions were loaded on SDS-gel. Western blot was performed using Penta·His Antibody as the first antibody**. (B)** Trypsin limited proteolysis of KdpD were performed at room temperature for indicated times. Reactions were stopped by adding the 5×SDS loading dye. Reaction mixtures (25µL) were subsequently loaded on SDS-gel. Stable band indicated with the arrow was cut and analysed by mass spectrometry. This stable fragment was found to be composed of KdpD 38-380. **(C)** *E. coli* BL21(DE3) carrying pBAD24-KdpD(Met+38-380)-6His was cultivated overnight in LB [with 0.1 % (w/v) arabinose] at the indicated temperatures. Cytoplasmic membrane and cytoplasm fractions were sparated as described in (A). After adding with 5×SDS loading dye into LB culture, resuspended membrane vesicles and cytoplasm fraction, 25µL of the mixtures were loaded on SDS-gel. Western blot was performed using KdpD polyclonal antiserum as the first antibody.

3.3.3 Assembly of *E. coli kinase* KdpD into nanodiscs for single particle cryo-EM

Compared to crystallization trials, the single particle cryo-EM might be more advisable for probing the structure of *kinase* KdpD protein. Membrane proteins may be extracted with detergent and visualized by cryo-EM directly in the micelles or after reconstitution into nanodiscs or liposomes (Vinothkumar 2015). Compared to nanodiscs, liposomes are easier to obtain, but much larger and less stable. Moreover, it is hard to accurately control the size and the lipid to protein ratio (Bayburt and Sligar 2010).

Assembly of KdpD protein into nanodiscs was preliminarily tested. There are several MSP available with increasing protein lengths such as MSP1, MSP1E1, MSP1E2, MSP1E3 (and their variants), which can support the assembly of nanodiscs with increasing diameters (for empty nandiscs, ranging from 9.5 to 12.8 nm) (Denisov, Grinkova et al. 2004). The empty nanodiscs with the MSP1E3D1 [MSP1E3 derivate, two slight differences from MSP1E3, **(i)** at the N-terminal end there is a 7-histidine tag instead of 6 His, and **(ii)** there is a TEV protease cleavage site following the 7-histidine tag)] as the belts have an average diameter of 12.1nm.

The MSP and *E. coli kinase* KdpD protein were purified separately as described in the chapter of Materials and Methods. As the first trial of nanodiscs assembly, the 7-His tag attaching to the MSP protein was kept for the point of future Western blot and total lipid extract of *E. coli* was used as the lipid substrate [other commonly used lipids are DPPC, DMPC and POPC (Nath, Atkins et al. 2007)] . The MSP and lipid were firstly mixed with a molar ratio of 1:130 and 4:130 to check the formation of empty nanodiscs. According to the estimated protein size (~163 kDa) (Figures 23B and 23D, blue arrow) via size-exclusion chromatography, the formation of empty nanodiscs seemed to be successful (theoretical size ~ 232 kDa). When the stoichiometric ratio was set to 1:130, most of the lipid and MSP were incorporated into liposomes (Figure 23C, red arrow marked peak on the grey curve; Figure 23D). When this ratio

was adjusted to 4:130, the formation of nanodiscs was promoted and the formation of liposomes diminished (Figure 23C, black curve).

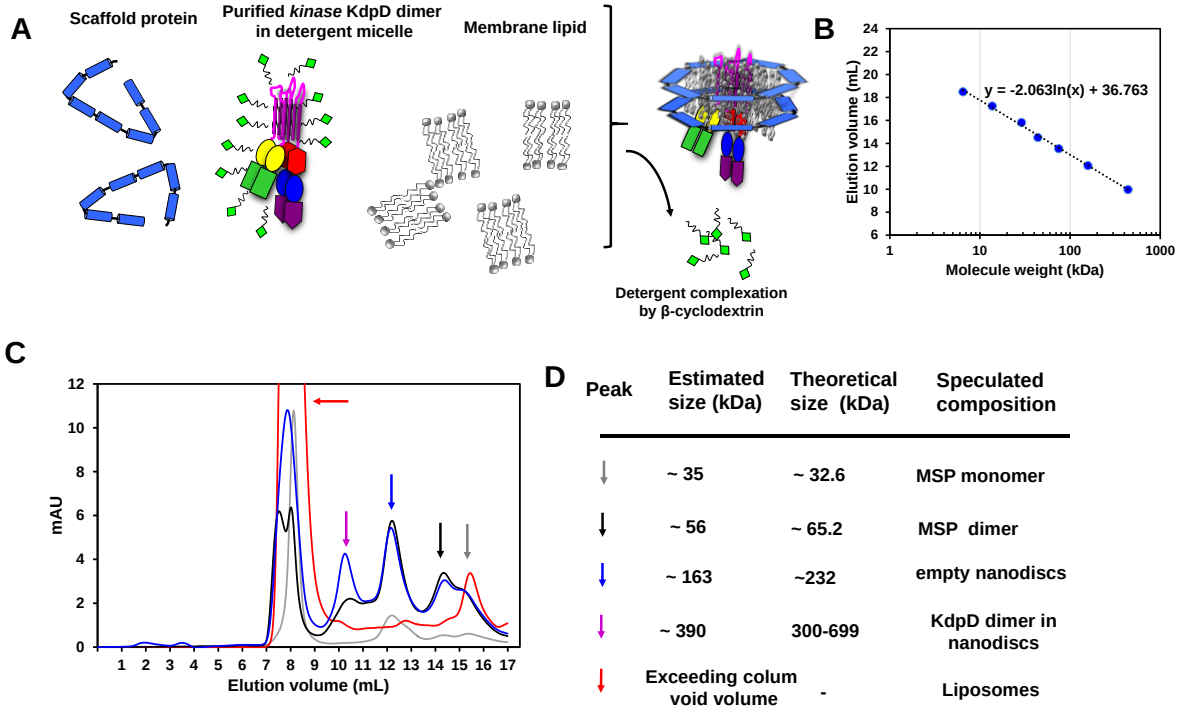

Figure 23: Integration of *E. coli kinase* KdpD into nanodiscs. (A) Schematic of assembling purified *kinase* KdpD into nanodiscs. **(B)** Calibration curve of Superdex 200 Increase 10/300 GL column for the size-exclusion chromatography. Column calibration was performed by the proteins were used for the calibration ferritin (440 kDa), aldolase (158 kDa), conalbumin (75 kDa), ovalbumin (44 kDa), carbonic anhydrase (29 kDa), ribonuclease (13.7 kDa) and aprotinin (6.5 kDa). **(C)** Size-exclusion chromatography analysis of four nanodiscs assembly mixtures. Grey and Black curves: MSP and lipid molar ratio = 1:130 and = 4:130, respectively [MSP should assemble into empty nanodiscs (blue arrow), liposomes (red arrow) and protein dimer (black arrow)]. Red and blue curves: KdpD, MSP and lipid molar ratio = 0.2:1:130 and = 0.05:4:130, respectively [MSP should assemble into empty nanodiscs and nanodiscs containing KdpD dimer (violet arrow), MSP dimer (black arrow)]. Moreover, KdpD may be attracted by lipids to form liposomes (red arrow), while some MSP stays as monomer (grey arrow)]. **(D)** Speculated composition of the peak fraction in (C), according to the estimated and theoretical molecule sizes.

In parallel, to assemble KdpD into nanodiscs, KdpD was added into the MSP and lipid mixture with two kinds of stoichiometric proportion, KdpD:MSP:lipid = 0.2:1:130 (Figure 23C, red curve) and 0.05:4:130 (Figure 23C, blue curve). To make the KdpD protein more accessible to lipid,

the wrapping detergent was chelated with four folds concentration of β-cyclodextrin (Hornschemeyer, Liss et al. 2016). According to the size-exclusion chromatography analysis, the stoichiometric proportion of 0.2:1:130 could not support the formation of empty nanodiscs or nanodiscs with KdpD dimer. Instead, all the KdpD proteins assembled with lipid as liposomes (Figures 23B and 23D, red arrows). When less KdpD protein and more MSP were supplied into the reaction mixture (stoichiometric proportion 0.05:4:130), two new peaks appeared, indicating empty nanodiscs and nanodics loaded with KdpD dimer, respectively (Figure 23C, blue and violet arrows on blue curve).

These results suggest KdpD dimer may have already been assembled into nanodiscs. However, when the fractions were evaluated with SDS-PAGE and Western blot, very faint signal was detected (data not shown). Further verifications are required.

3.3.4 Exploring CipA and CipB as scaffolds for *in vivo* crystallization

In addition to the common methods to get the structure of KdpD, *in vivo* crystallization offers another opportunity. Since both *kinase* and *non-kinase* KdpD are targeted to cytoplasmic membrane, in order to get the KdpD proteins crystallized, a scaffold protein is required to keep in them cytosol.

It has been known that CipA and CipB form independent PCIs with different shapes in *P. luminescens* (Bintrim and Ensign 1998, Bowen and Ensign 2001). But there is no report whether they would function as a scaffold to bring heterogeneous proteins into PCIs. In order to verfy this speculation, the *cipA* or *cipB* genes was first deleted individually. Basing on the single deletion of *cipA* and *cipB*, *cipA*$^{-}$ *cipB*$^{-}$ double deletion mutant of *P. luminescens* was aslo generated and designated as *P. luminescens cip*$^{-}$ (see materials and methods). This strain could be used for production of *in vivo* crystals of desired proteins.

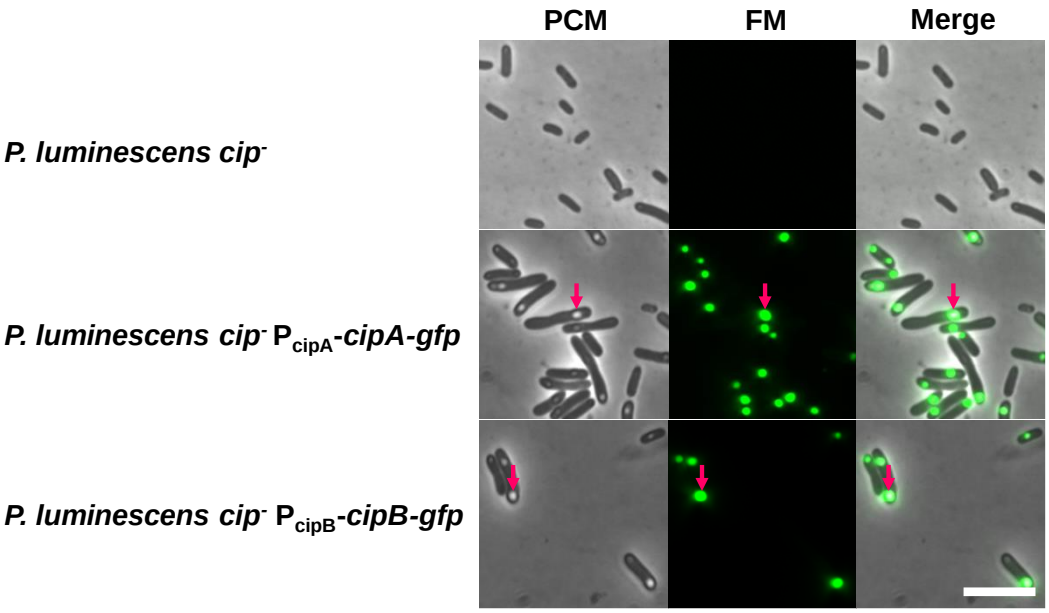

Figure 24: CipA-GFP and CipB-GFP hybrids are organized into PCIs in *P. luminescens cip*- cells. After 56 h of growth on LB plates at 30°C, *P. luminescens cip*-, *P. luminescens cip*-, *P. luminescens cip*- P_{cipA}-*cipA-gfp*, *P. luminescens cip*- P_{cipB}-*cipB-gfp* cells were collected and resuspended in fresh LB medium for microscopy. The fusion genes *cipA-gfp* and *cipB-gfp* were expressed under the control of the native promoters of *cipA* and *cipB*, respectively. Arrows indicate PCIs. PCM, phase-contrast microscopy; FM, fluorescence microscopy. Scale bar, 7.5 µm.

The scaffold funcation of CipA and CipB was subsequently evaluated via organizing the GFP reporter into PCIs. Gene fusions *cipA-gfp* or *cipB-gfp* (under control of their respective native promoters) coding either for CipA-GFP or CipB-GFP, were integrated into the chromosome of *P. luminescens cip*-. Then, the cells were grown for 56 h on LB agar at 30°C, and *in vivo* formation of fluorescent CipA-GFP or CipB-GFP PCIs were observed (Figure 24). This experiment proves that both CipA and CipB can act independently as scaffolds in their native host.

Subsequently, the CipA, CipB, CipA-GFP and CipB-GFP was isolated as shown in Figure 7, and shipped to the collaborator Dr. Lars Redecke (Universitäten Lübeck und Hamburg, current position Universität zu Lübeck) for serial crystallography synchrotron beamline SPring-8

(Japan). Unfortunately, diffraction pattern was only observed from the CipB PCIs (at resolution of 6 Å, data not shown).

It is conceivable that larger *in vivo* PCIs may support better diffractions. In order to get lager PCIs, the vectors pFastBac1-cipA-gfp and pFastBac1-cipA-gfp were constructed. CipA-GFP and CipB-GFP hybrid proteins were subsequently produced in Sf9 insect cells from the polyhedrin (P_H) promoter, by the collaborator Dr. Lars Redecke. Even though the *in vivo* assembly of these two proteins were observed. The roundish complexes are analogous to the organelles of eukaryotic cells, but are not PCIs (Figure 25). Therefore, they could not be used as crystals for protein structural analysis.

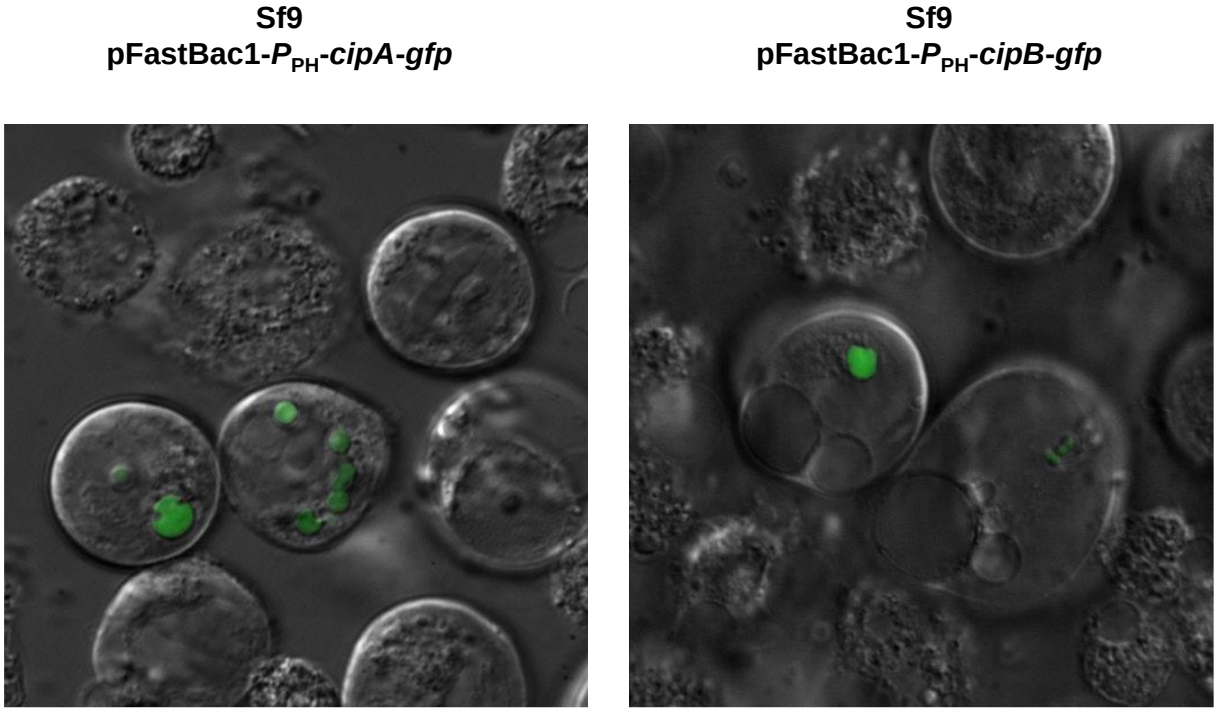

Figure 25: CipA-GFP and CipB-GFP assemble into roundish complexes in the insect cells. (A) CipA-GFP, **(B)** CipB-GFP. Gene fusions *cipA-gfp* and *cipB-gfp* were expressed from the baculovirus polyhedrin (P_H) promoter in insect Sf9 cell line.

3.4 Evaluation of CipA and CipB as protein scaffolds for biotechnological applications

3.4.1 Cip scaffolds bring single proteins into PCIs

3.4.1.1 CipA-6His and CipB-6His form PCIs in *E. coli*

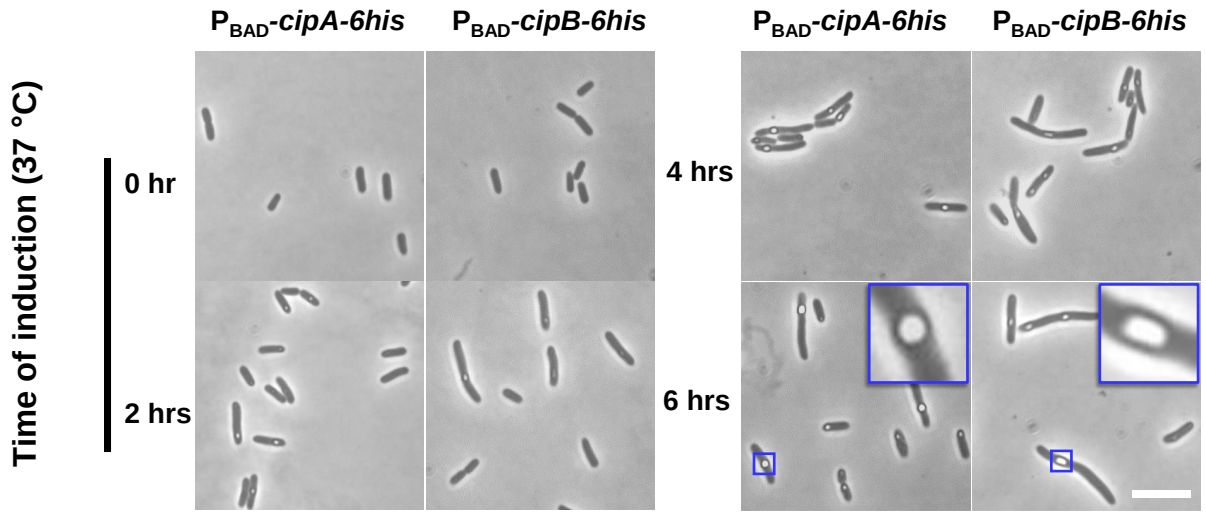

Figure 26: CipA-6His and CipB-6His self-organize into PCIs in *E. coli* DH5α. Production of CipA-6His and CipB-6His in *E. coli* DH5α was induced with 0.2% (w/v) L-arabinose at 37°C, when the cell density reached OD_{600}=0.6. Cells were subsequently analyzed every 2 h by microscopy. The PCIs in the areas marked by the small boxes (bottom row) are shown at higher magnification at the top right.

Formation of CipA-GFP and CipB-GFP PCIs in *P. luminescens* generally takes 2-3 days (Figure 24), and the factors that control the native *cip* promoters are still unknown. To circumvent these drawbacks the Cip scaffolds were tested in *E. coli*. First, *cipA-his* and *cipB-his* were expressed in *E. coli* DH5α under the control of the arabinose inducible promoter P_{BAD}. When cells were grown at 37°C, PCIs with diameters of 0.1-0.3 µm were detected by phase-contrast microscopy after induction of fusion gene expression with L-arabinose for 2 h (Figure 26). This confirmed that PCIs can be produced heterologously in *E. coli*.

3.4.1.2 Cip organize GFP into PCIs in *E. coli*

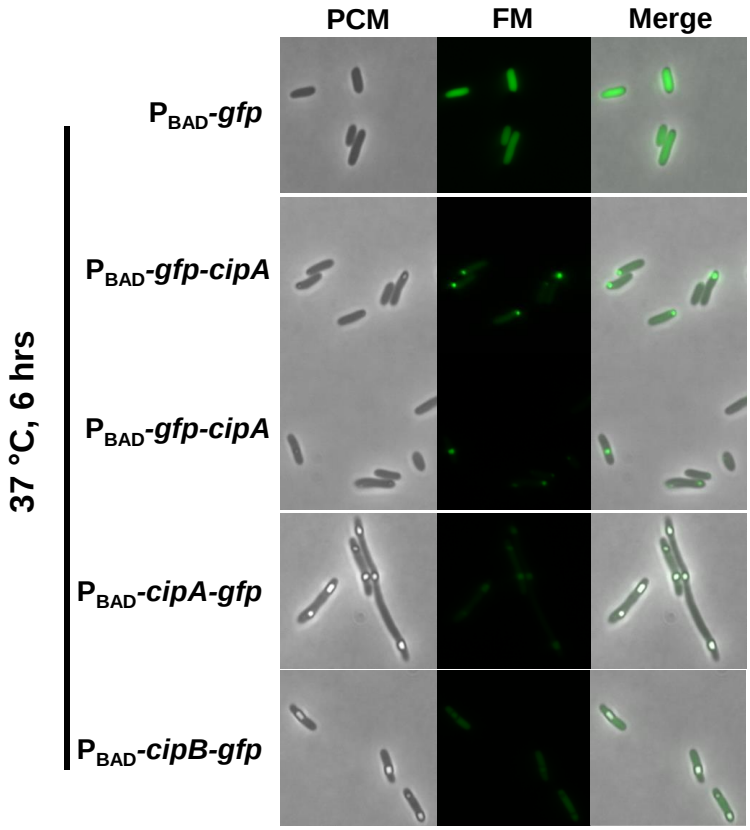

Figure 27: Production of CipA-GFP and CipB-GFP PCIs at 37°C**.** *E. coli* DH5α was induced with 0.2% (w/v) L-arabinose at 37°C, when the cell density reached OD_{600}=0.6. Cells were subsequently analyzed by microscopy 6 h after the supplement of L-arabinose.

GFP produced in *E. coli* is normally homogenously distributed (Figure 27). Cip scaffolds were then tested for their competences of subcellularly organize GFP. CipA-GFP and CipB-GFP, GFP-CipA and GFP-CipB were produced at different growth temperatures in *E. coli*. As shown in Figure 27, with the assistance of Cip scaffolds, GFP can be assemble into PCIs.

When the Cip scaffolds was placed to the C-terminal of GFP, very small fluorescent foci were observed. When the Cip scaffolds placed to the N-terminal of GFP, very large PCIs form in *E. coli* cells, while they are barely fluorescent (Figure 27). Therefore in the following experiments, Cip scaffolds are uniformly placed to the N-terminal of interested proteins.

3.4.1.3 Temperature impact on the formation of PCIs in *E. coli*

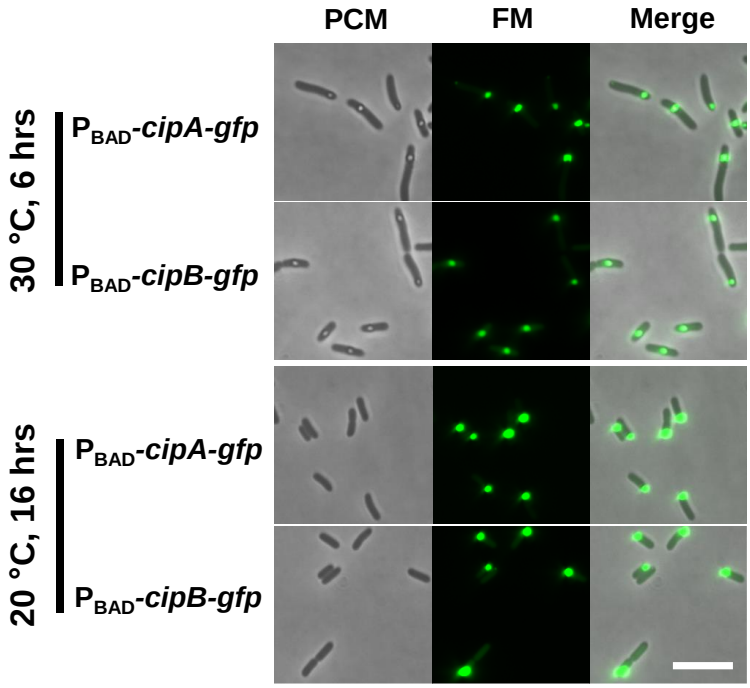

Figure 28: Production of fluorescent GFP complex at lower temperature. Production of CipA-GFP and CipB-GFP in *E. coli* DH5α was induced with 0.2% (w/v) L-arabinose at 30°C and 20°C, respectively, when the cell density reached OD_{600}=0.6. Cells were analyzed by microscopy 6 h after the supplement of L-arabinose.

As shown above cells grown at 37°C had highly refractile, but weakly fluorescent GFP PCIs (Figure 27). When cells were grown at 30°C, phase-bright and fluorescent CipA-GFP or CipB-GFP PCIs were detectable (Figure 28). A further decrease in the growth temperature to 20°C permitted subcellular organization of CipA-GFP and CipB-GFP hybrids to be visualized as highly fluorescent areas, which were not detectable in phase-contrast micrographs (Figure 28).

These results suggest that the protein complexes formed at 30°C/37°C are densely organized and therefore can shift the phase of incident light, whereas the complexes produced at 20°C seem to be less tightly packed. The low fluorescence of PCIs produced at 37°C is likely to be the result of rapid assembly of the CipA-GFP or Cip-GFP molecules, which might exceed the maturation rate of the chromophores.

3.4.1.4 Impact of inducer concentration on the formation of PCIs

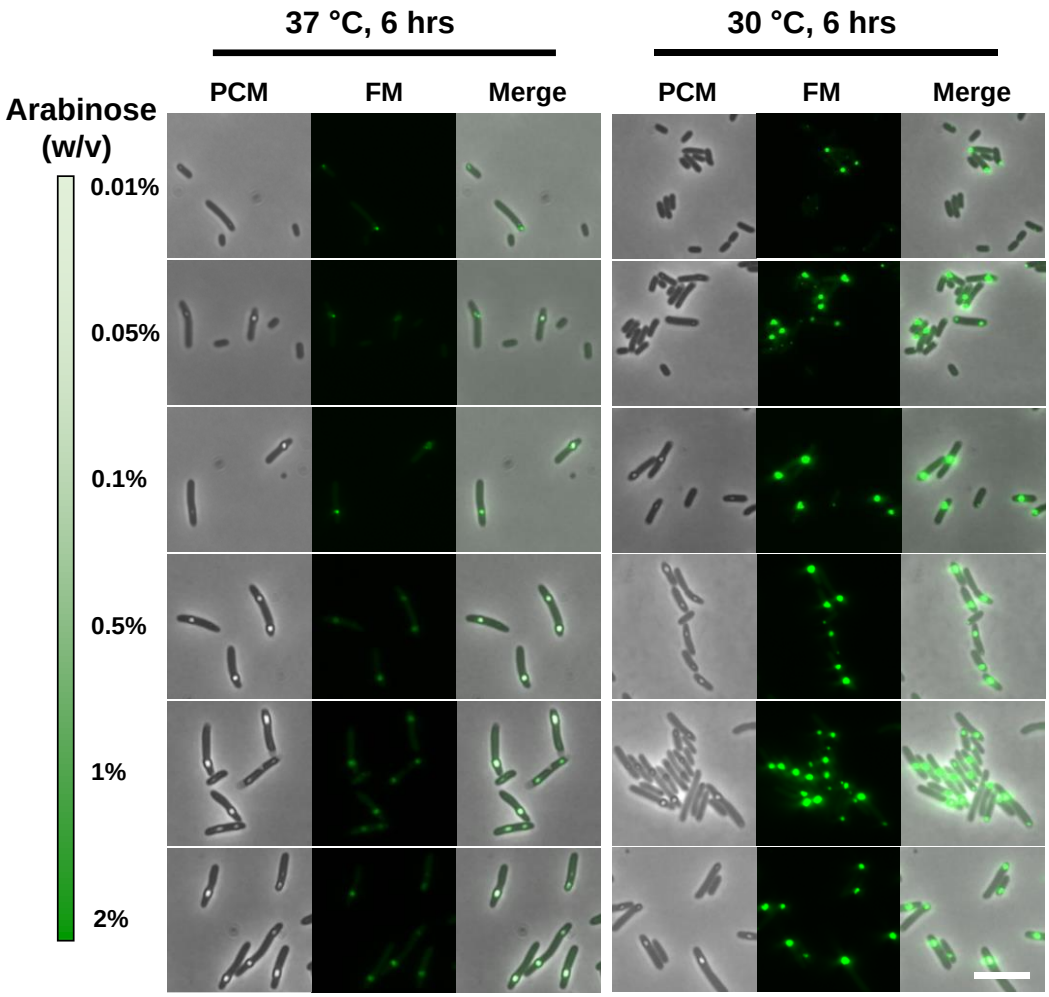

Figure 29: Influence of inducer concentration on formation of CipA-GFP PCIs in *E. coli*. The cultivation procedure (at 37°C or 30°C) was the same as described in Figure 27, but different L-arabinose concentrations [from 0.01% to 2% (w/v)] were tested. PCM, phase-contrast microscopy; FM, fluorescence microscopy. Scale bar, 7.5 µm.

In addition to the temperature, the effect of inducer concentration was also test on Cip scaffolds protein organization. When the L-arabinose concentration was reduced to 0.05% (w/v) or 0.01% (w/v), the PCIs formed by CipA-GFP were quite smaller, but their fluorescence intensity was not affected (Figure 29). This result implies that the inducer concentration has an impact on the rate of synthesis of CipA-GFP molecules, but - unlike temperature - has no influence on the organization of the hybrid protein.

3.4.1.5 *In vivo* stability of the GFP PCIs

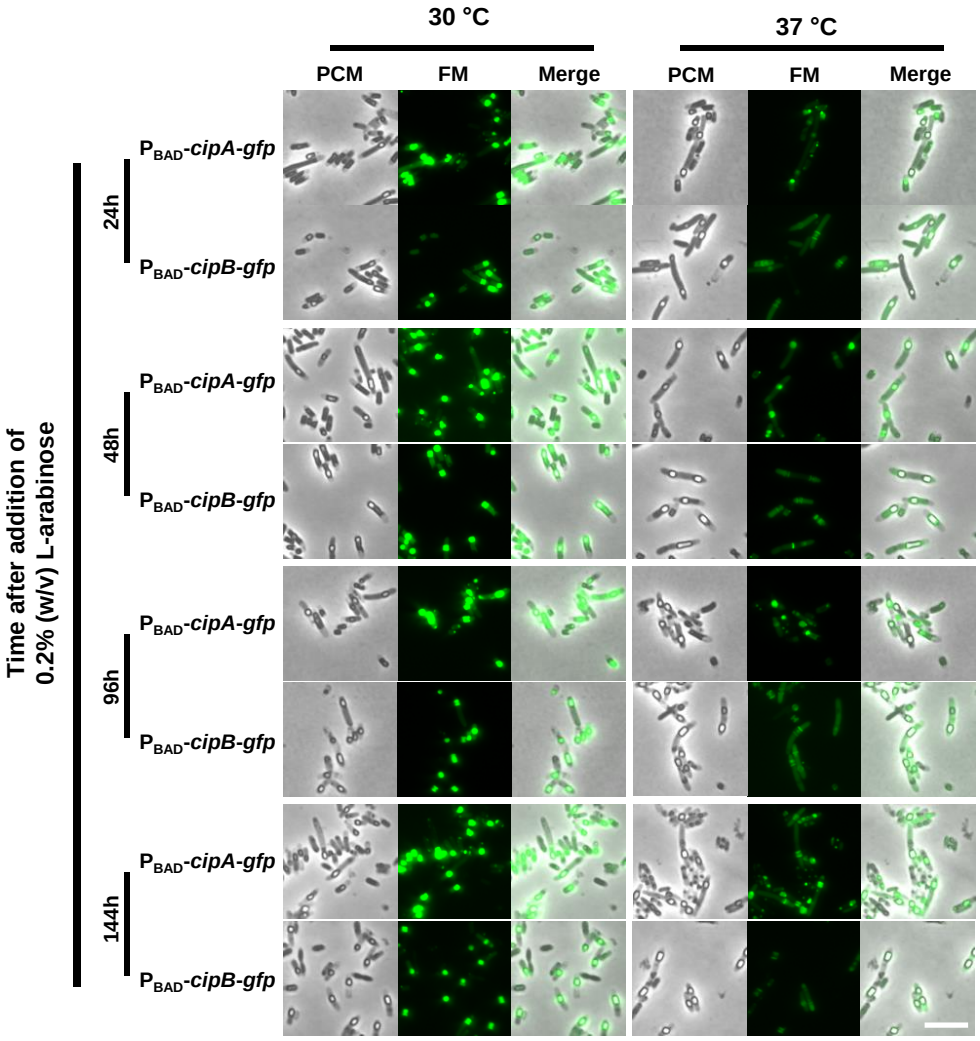

Figure 30: Stability of CipA-GFP and CipB-GFP PCIs in *E. coli* cells. Production of the CipA-GFP and CipB-GFP PCIs in *E. coli* was initiated as described by addition of 0.2% (w/v) L-arabinose (PCM, phase-contrast microscopy; FM, fluorescence microscopy). Cultures were grown at 30°C and 37°C, respectively. Scale bar, 7.5 µm.

To study the PCIs stability *in vivo*, the production of the GFP PCIs was induced at 30 and 37°C as described in Figures 27 and 28, but the cultivation time was much more extended. During this period, there was no fresh medium was provided for the PCI producing cell. Cells were checked at the indicated timepoints (Figure 30). After 6 days cultivation, the PCIs are still clearly visible. This results indicates that the PCIs are very stable *in vivo*.

3.4.1.6 Formation of PCIs in defined medium

In addition to the LB medium, a defined medium modified from M9 medium (Noyes, Meng et al. 2008), can also support the formation of PCIs in *E. coli* cells. As shown in Figure 31, CipA-GFP and CipB-GFP assembled into fluorescent PCIs that were clearly visible under the microscope. This offers the opportunity to balance and apply advanced feeding schemes. Because for large scale factory productions, cheaper and poorer media are commonly used than the medium used in the laboratory.

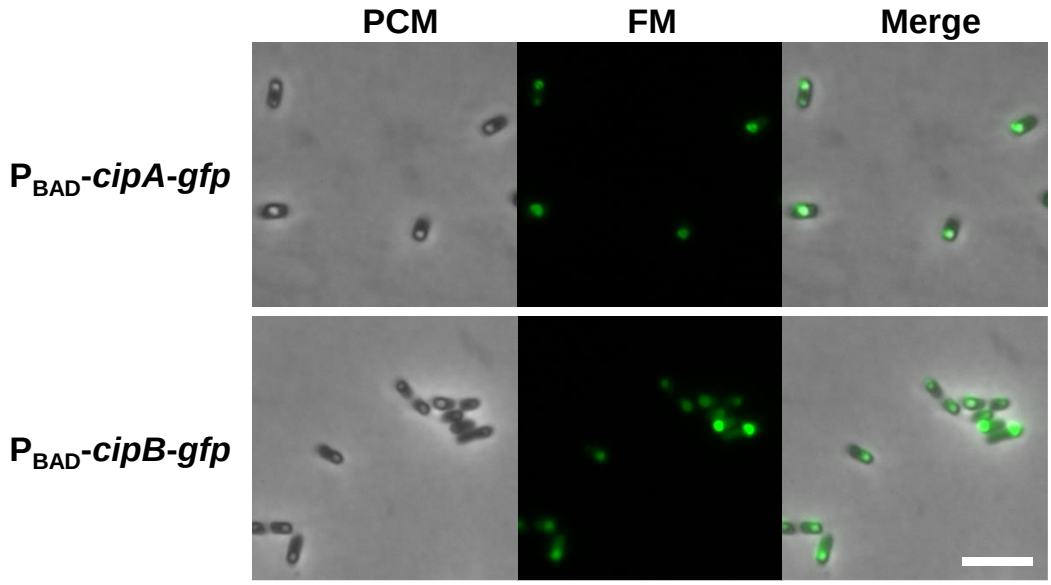

Figure 31: Cip scaffolds organize GFP into PCIs in *E. coli* cells cultivated in a defined medium (Noyes, Meng et al. 2008)**.** Production of CipA-GFP and CipB-GFP at 37°C was induced with 0.2% (w/v) L-arabinose at the beginning of cultivation. Micrographs were taken after 16 hours of induction. PCM, phase-contrast microscopy; FM, fluorescence microscopy. Scale bar, 7.5 µm.

3.4.1.7 Isolation and characterization of CipA-GFP and CipB-GFP PCIs from *E. coli*

To isolate CipA-GFP and CipB-GFP PCIs from *E. coli*, cells were passed three times through a French press at 0.4 kbar. Then the PCIs were collected by centrifugation and washed three times with Na-phosphate buffer (Figure 7). CipA-GFP and CipB-GFP protein complexes

produced at 20°C could not be isolated by this procedure as they broke up during cell disruption and could not be pelleted by centrifugation (Figure 32A).

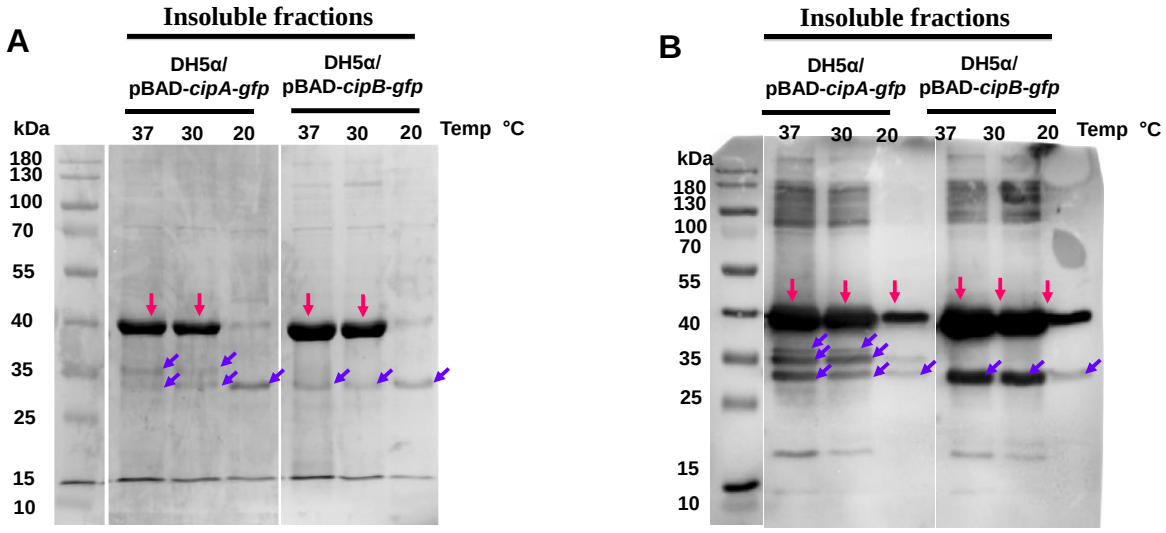

Figure 32: SDS-PAGE and Western blot of the CipA-GFP and CipB-GFP protein complexes. *E. coli* cells were cultivated at 37°C, 30°C and 20°C to produce CipA-GFP and CipB-GFP complexes as described in Figures 27 and 28. Cells were collected and lysed as described in Figure 7. Insoluble fractions were collected and washed three times with Na-phosphate buffer, and resuspended in an equal final volume compared to the supernatant. Equal volumes (24 µL) of washed pellets were loaded on the SDS-PAGE. Gels were stained with Coomassie Brilliant Blue R-250 **(A)** or applied to Western blot using anti-GFP antibody **(B).** Magenta and blue arrows mark CipA-GFP and CipB-GFP monomers and early translation termination or protein degradation bands, respectively.

To check the purities of the isolated PCIs, the insoluble fractions were applied to SDS-PAGE. As shown on the stained SDS-gels, the isolated PCIs were already about 90% pure (Figure 32A). However, some bands that may indicate early translation termination or protein degradation were observed when the isolated PCIs were analyzed by Western blot with anti-GFP antibody (Figure 32B). The early translation termination or protein degradation seems not to be affected by different cultivation temperatures.

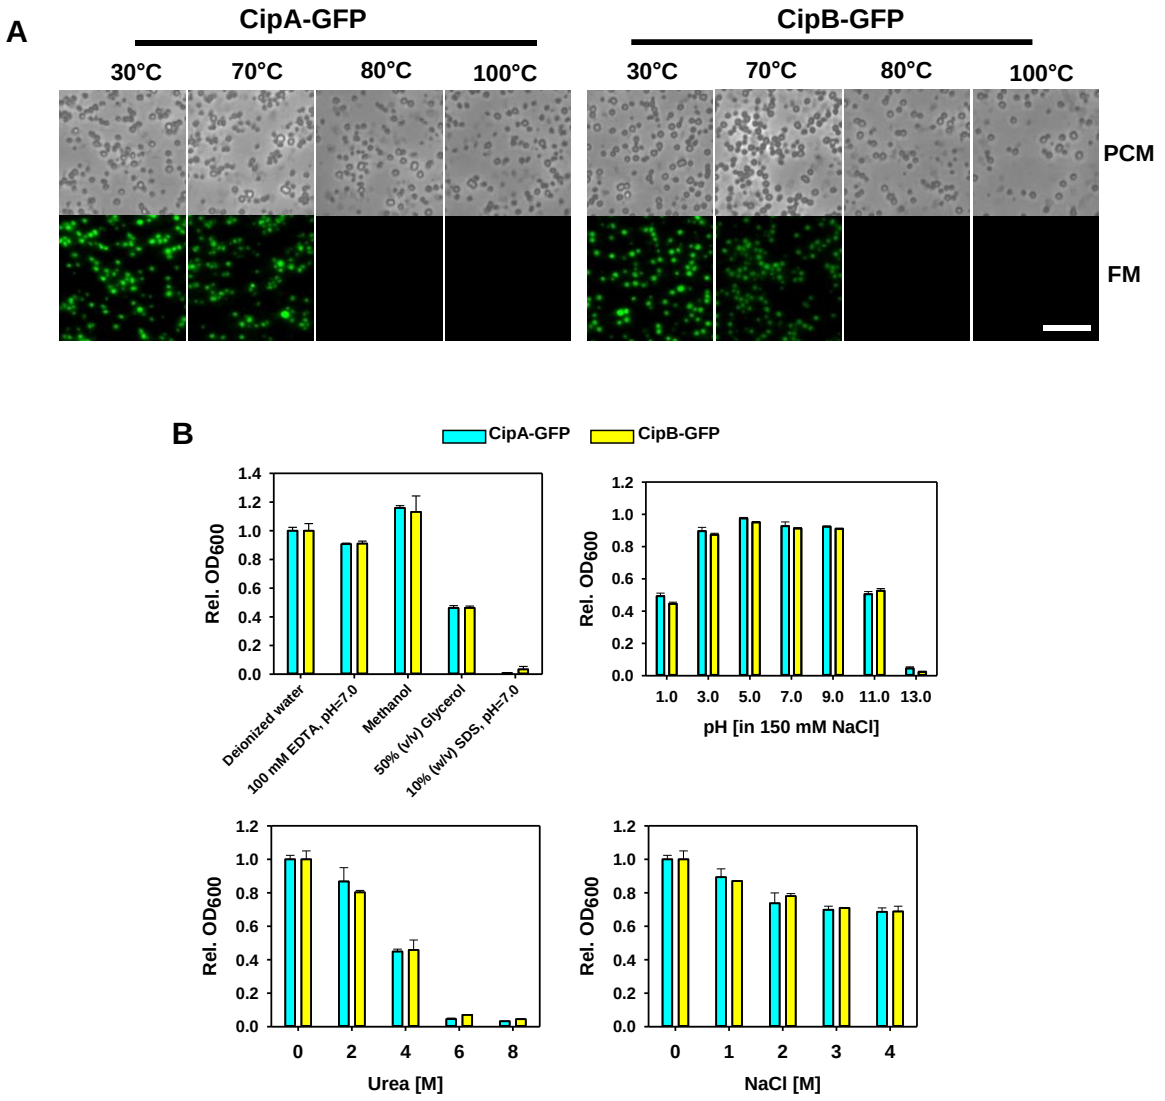

Figure 33: Isolation and characterization of GFP PCIs. (A) Thermal stability of isolated PCIs. Micrographs were taken after a 10-min incubation at the indicated temperature (PCM, phase contrast microscopy; FM, fluorescence microscopy). Scale bar, 7.5 µm. **(B)** Solubility of PCI in various solutes. The degree of solubilization of PCIs was estimated by the relative decrease in initial optical density. The value for PCIs in deionized water was set to 1.0.

To study their thermal stability, the isolated PCIs were exposed to different temperatures for 10 min. It was found that the fluorescence signals emitted by CipA-GFP and CipB-GFP PCIs vanished at 80°C, but PCIs remained structurally undisturbed even after 10 min at 100°C (Figure 33A). Thus, high temperature affects the activity of the tagged protein or enzyme but does not influence PCI structure *per se*.

To determine their solubility, CipA-GFP and CipB-GFP PCIs were resuspended in different solutions. The initial optical density (OD_{600}) was measured and any subsequent decrease was taken to reflect solubilization of PCIs (Figure 33B). It was found that PCIs could be dissolved in denaturing solutions such as 10% (w/v) SDS or 8 M urea, and under acidic (pH 3) or alkaline (pH 11) conditions, but also (partially) in 50% (v/v) glycerol. In contrast, high concentrations of NaCl or EDTA had no effect (Figure 33B).

In fact, PCIs organized by Cip scaffolds, like many other crystals produced *in vivo*, differ markedly in some physical characteristics from crystals produced *in vitro*. For example, the crystals of *Trypanosoma brucei* cathepsin produced in Sf9 insect cells have been reported to be stable in deionized water, salt solutions or alkaline buffers, but soluble in buffers at, pH below 4 (Koopmann, Cupelli et al. 2012). Bt crystals also remain stable in mildly acidic conditions, but can be dissolved at alkaline, pH (Sawaya, Cascio et al. 2014). In summary, it has been clearly shown that the Cip-based PCIs produced *in vivo* are very stable. Easy isolation of stable proteins is an essential prerequisite for most biotechnological applications *in vitro*.

3.4.1.8 Cip scaffolds organize LacZ into enzymatically active PCIs

In the next step, the β-galactosidase (LacZ) derived from *E. coli* was tagged separately with CipA and CipB and produced in *E. coli* DH5α at 37°C. Similarly, CipA-LacZ and CipB-LacZ were organized into refractile PCIs (Figure 34A), which could be isolated as easily as the CipA-GFP and CipB-GFP PCIs. In parallel, soluble 6His-tagged LacZ (His-LacZ) was purified by affinity chromatography. In the next step, enzymatic activities were determined. Yields of CipA-LacZ and CipB-LacZ were higher relative to that of the soluble His-LacZ (Figure 34B). Conversely, the specific activity of the soluble His-LacZ was higher than that of Cip-tagged LacZ. This might indicate that only molecules on the surface of PCIs are accessible to the substrate *o*-nitrophenyl-β-D-galactopyranoside.

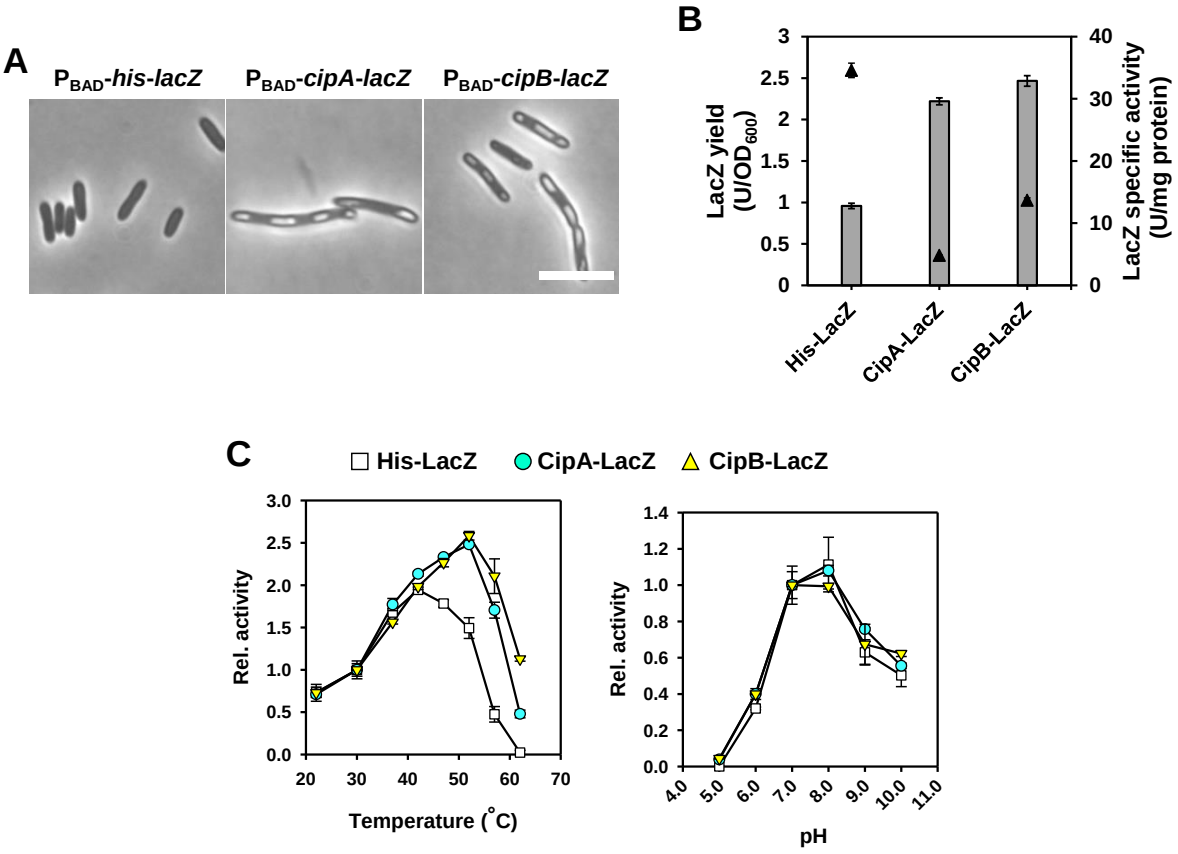

Figure 34: Cip scaffolds organize LacZ into PCIs in *E. coli*. (A) Micrographs of His-LacZ, CipA-LacZ or CipB-LacZ-producing *E. coli* cells. Synthesis of His-LacZ, CipA-LacZ or CipB-LacZ in *E. coli* DH5α was induced with 0.2% (w/v) L-arabinose at 37°C for 6 h (scale bar, 7.5 µm). **(B)** LacZ yield (grey column) and specific activity (black triangle) of His-LacZ, CipA-LacZ PCIs and CipB-LacZ PCIs. **(C)** Effects of temperature and, pH on the activity of His-LacZ, CipA-LacZ PCIs and CipB-LacZ PCIs. The β-galactosidase activity measured at 30°C and, pH 7.0, respectively, was set to 1.0.

The optimum temperature for His-LacZ activity was determined to be 42°C, while the activities of CipA-LacZ and CipB-LacZ PCIs peaked at 52°C (Figure 34C, left). The, pH profiles were similar for LacZ in soluble and PCI forms, all showing an optimal activity at, pH 8.0 (Figure 34C, right). This demonstrates that Cip scaffolds are useful tools to stabilize enzymes. Furthermore, Cip scaffolds can functionally organize proteins of large size (LacZ = 116 kDa) into PCIs.

3.4.2 Cip scaffolds bring multiple proteins into PCIs

3.4.2.1 Cip scaffolds co-organize GFP and LacZ into bioactive PCIs

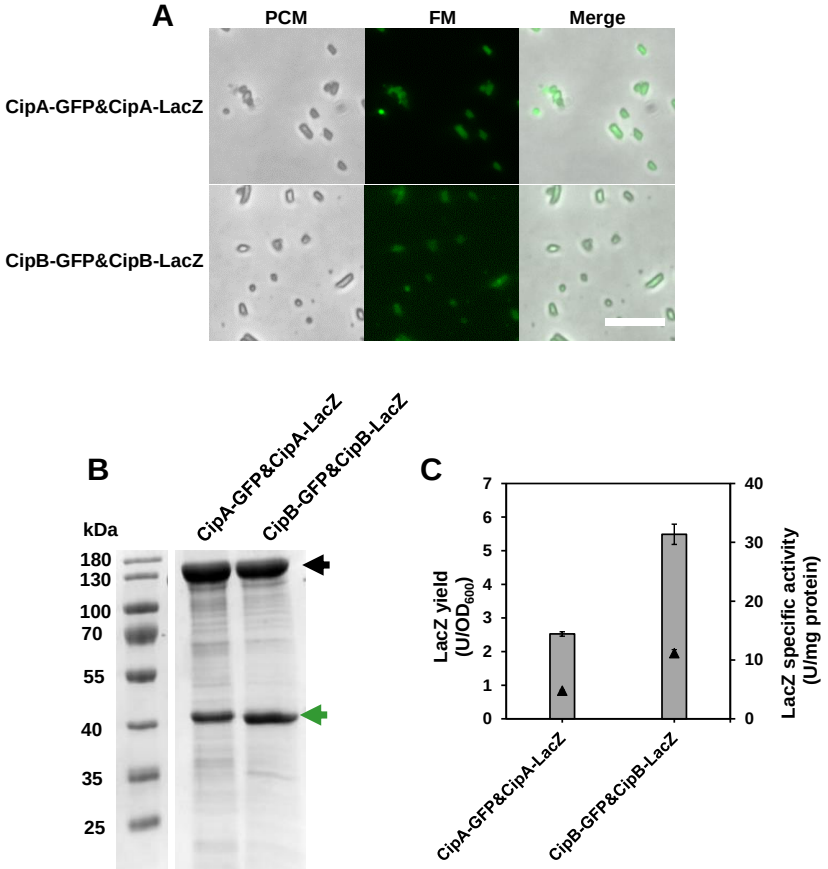

Figure 35: Cip scaffolds co-organize GFP and LacZ into PCIs in *E. coli*. (A) Isolated CipA-GFP&CipA-LacZ and CipB-GFP&CipB-LacZ PCIs. CipA-GFP and CipA-LacZ or CipB-GFP and CipB-LacZ were co-produced as PCIs, which were released from the cells as described in methods. Scale bar, 7.5 µm. **(B)** SDS-PAGE of CipA-GFP&CipA-LacZ and CipB-GFP&CipB-LacZ PCIs. The black arrow indicates CipA-LacZ or CipB-LacZ and the green arrow indicates CipA-GFP or CipB-GFP. **(C)** β-Galactosidase yields (grey column) of CipA-GFP&CipA-LacZ and CipB-GFP&CipB-LacZ PCIs and their corresponding specific activities (indicated by the black triangle).

Most metabolic pathways employ multiple enzymes to transform substrates into products. It will be interesting to know, in addition to organizing single types of proteins, Cip scaffolds could also co-organize multiple proteins. For this purpose, GFP and LacZ (two reporter proteins that share no sequence or structural similarity and differ in molecular weight) were tagged separately with CipA and CipB. CipA-GFP and CipA-LacZ or CipB-GFP and CipB-LacZ were

produced in combination in *E. coli* and the PCIs were isolated as described above and analyzed by microscopy.

It was found that each of the isolated PCI particles was fluorescent (Figure 35A), indicating that GFP molecules had been incorporated into all PCIs. The isolated PCIs were also analyzed by SDS-PAGE, which clearly revealed two major bands corresponding to CipA-LacZ (or CipB-LacZ) and CipA-GFP (or CipB-GFP) in similar molar ratios (Figure 35B). Moreover, the isolated PCIs also had similar β-galactosidase activities (Figure 35C). Thus, it could be concluded that Cip scaffolds can organize GFP and LacZ proteins into mixed PCIs, which are both fluorescent and enzymatically active. This suggested that Cip scaffolds might also be capable of organizing multiple enzymes into metabolic pathways.

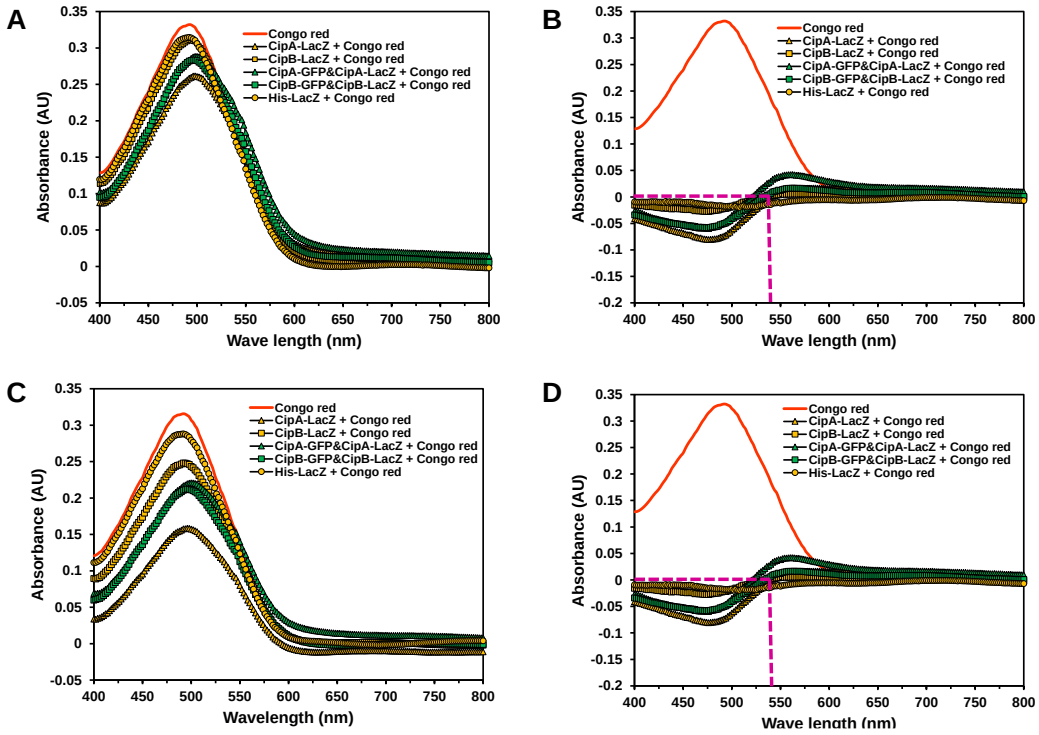

Figure 36: Congo Red absorption spectra shift assay. LacZ PCIs and the soluble His-LacZ were incubated separately with Congo Red for 30 min [**(A)** and **(B)],** and 16 hours [**(C)** and **(D)**]. No spectral shift was detected by measuring the absorbance spectra [(A) and (C)]. No obvious difference was detected on the difference spectra at the wavelengths around 540nm [(B) and (D) (marked with magenta dash lines)].

LacZ PCIs in Figure 34 and Figure 35 show much decreased specific activities. This raises the question whether the CipA-LacZ and CipB-LacZ molecules are mis-folded and the PCIs are protein inclusion bodies. Before further experiment, this speculation needed to be verified. Protein inclusion bodies are generally rich of β-sheet structure (cross-β structure) (Fink 1998, Wang 2009). Such kind of structure can be detected by measuring the absorption spectra of Congo Red (Wang, Maji et al. 2008, Upadhyay, Murmu et al. 2012). Congo Red alone exhibits maximum light absorbance at the wavelength of 490 nm. Upon binding to the repeated β-sheet structure in the inclusion body, its maximum light absorbance will be shifted to longer wave length of around 540 nm.

The absorption spectra of Congo Red supplemented with CipA-LacZ, CipB-LacZ, CipA-GFP&CipA-LacZ or CipB-GFP&CipB-LacZ PCIs as well as the soluble protein His-LacZ were separately measured with the procedure described by Upadhyay *et al* (Upadhyay, Murmu et al. 2012). No specific spectral shift, which would indicate the repeated β-sheet structure in an inclusion body, was observed when the incubation time was extended to 16 hours (Figure 36). This proves that the PCIs are different from inclusion bodies.

3.4.2.2 The CipA scaffold brings together multiple enzymes involved in violacein biosynthetic pathway

To prove that Cip scaffolds can be used to organize multiple enzymes required for successive steps in a biosynthetic pathway and thus to enhance metabolite production, the enzymes of the violacein biosynthetic pathway (Vio enzymes) were separately tagged with the CipA scaffolf. Violacein is a bisindole compound that is naturally produced by several Gram-negative bacteria i.e*. Chromobacterium violaceum*, *Janthinobacterium lividum* and *Pseudoalteromonas tunicata.* Due to its potential applications in medicine, its complex synthetic pathway has been well studied.(Sanchez, Brana et al. 2006, Hoshino 2011) Violacein synthesis starts from L-tryptophan, and involves the five enzymes VioA, VioB, VioE, VioC, VioD (Vio enzymes) (Figure

37A). Protodeoxyviolaceinic acid is the common precursor of violacein and deoxyviolacein. Deoxyviolacein is an unwanted product, as its formation reduces the amount of protodeoxyviolaceinic acid available for synthesis of violacein (Figure 37A). Organization of the Vio enzymes with the aid of a CipA-based scaffold should bring the Vio enzymes close together in space, which in turn might increase the intermediate concentration close to the enzyme active sites and facilitate the rapid conversion of unstable metabolites.

A series of production strains, designated *E. coli* Vio1-Vio6, were generated in which none (Vio1), all (Vio6) or some (Vio2, Vio3, Vio4, Vio5) of the five enzymes in the pathway were individually fused to CipA (Figure 37B).

VioA and VioB are the two enzymes that catalyze the two-step conversion of L-tryptophan into indole-3-pyruvic acid imine dimer. The intermediate produced by VioA, indole-3-pyruvic acid imine, could be easily hydrolyzed.(Sanchez, Brana et al. 2006) Therefore, VioA and VioB were combined (strains *E. coli* Vio2, Vio3 and Vio6) with the aim to promote rapid conversion of indole-3-pyruvic acid imine into the dimer. VioC, VioD and VioE catalyze the downstream part of the metabolic pathway. The intermediates protodeoxyviolaceinic acid and protoviolaceinic acid are also very unstable.(Hoshino 2011) Therefore, VioC, VioD, VioE were combined in strains *E. coli* Vio5 and *E. coli* Vio6 to promote the rapid conversion of these intermediates. Finally, VioC is the most special Vio enzyme. It is not only required for conversion of protoviolaceinic acid into violacein, but is also involved in converting protodeoxyviolaceinic acid into the side product deoxyviolacein. Therefore, strains were designed to include VioC into the PCIs (*E. coli* Vio5 and Vio6) or to exclude it from the PCIs (*E. coli* Vio2, *E. coli* Vio3 and *E. coli* Vio4). The corresponding genes were placed under the control of the P_{BAD} promoter.

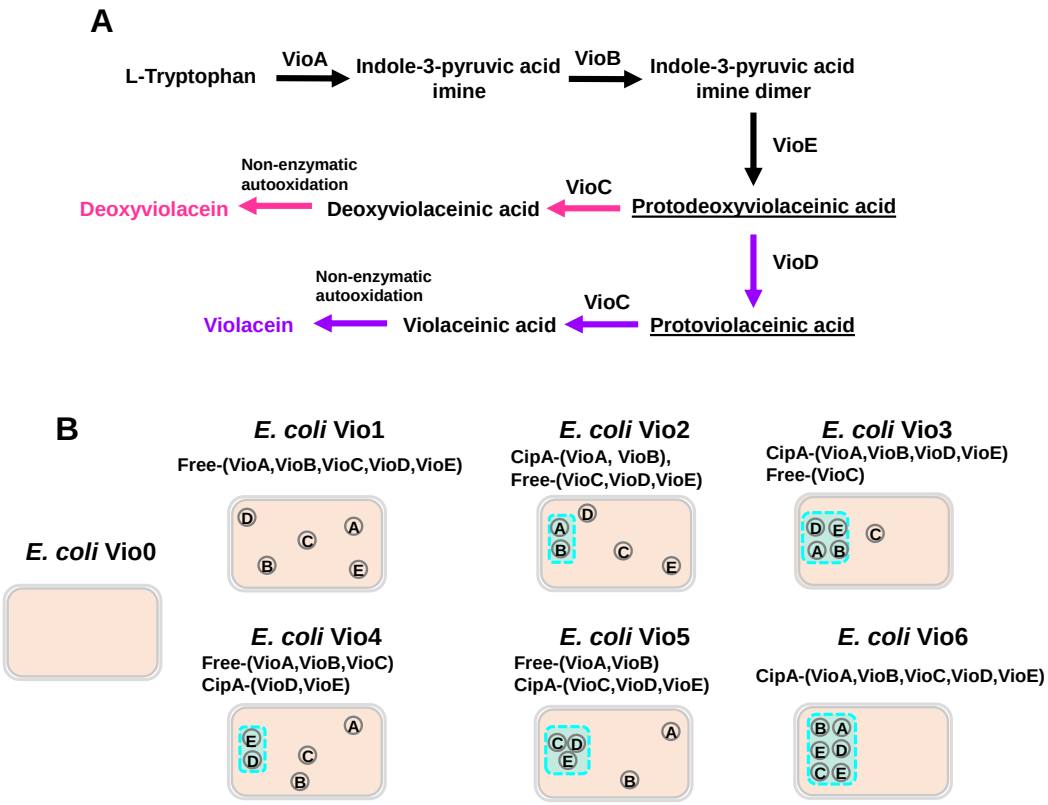

Figure 37: Engineering the violacein production metabolic pathway. (A) The biosynthetic pathway that converts L-tryptophan into violacein. The underlined compounds are reported to be very unstable intermediates. **(B)** Vio enzymes framed with box were separately tagged by CipA to be brought together into PCIs

First, appropriate inducer concentration for violacein production was determined the. Cultures of the engineered strains (*E. coli* Vio1 to *E. coli* Vio6) in early exponential phase were diluted with LB to an OD_{600} of 0.05 and drops were placed on LB plates containing 0%, 0.01%, 0.02%, 0.05%, 0.1% and 0.4% (w/v) of L-arabinose. After overnight cultivation at 30°C, the appropriate inducer concentration was found to be in the range of 0.01% (w/v) to 0.05% (w/v) according to the pigment accumulation (Figure 38A). The violacein production was induced with 0.01% (w/v) and 0.05% (w/v) L-arabinose. *E. coli* Vio4 and *E. coli* Vio5 produced more violacein and deoxyviolacein with 0.05% (w/v) L-arabinose while the other strains show less difference in the yields between these two inducer concentrations (Figure 38C). Therefore, unless specidied, violacein production was induced with 0.05% (w/v) L-arabinose.

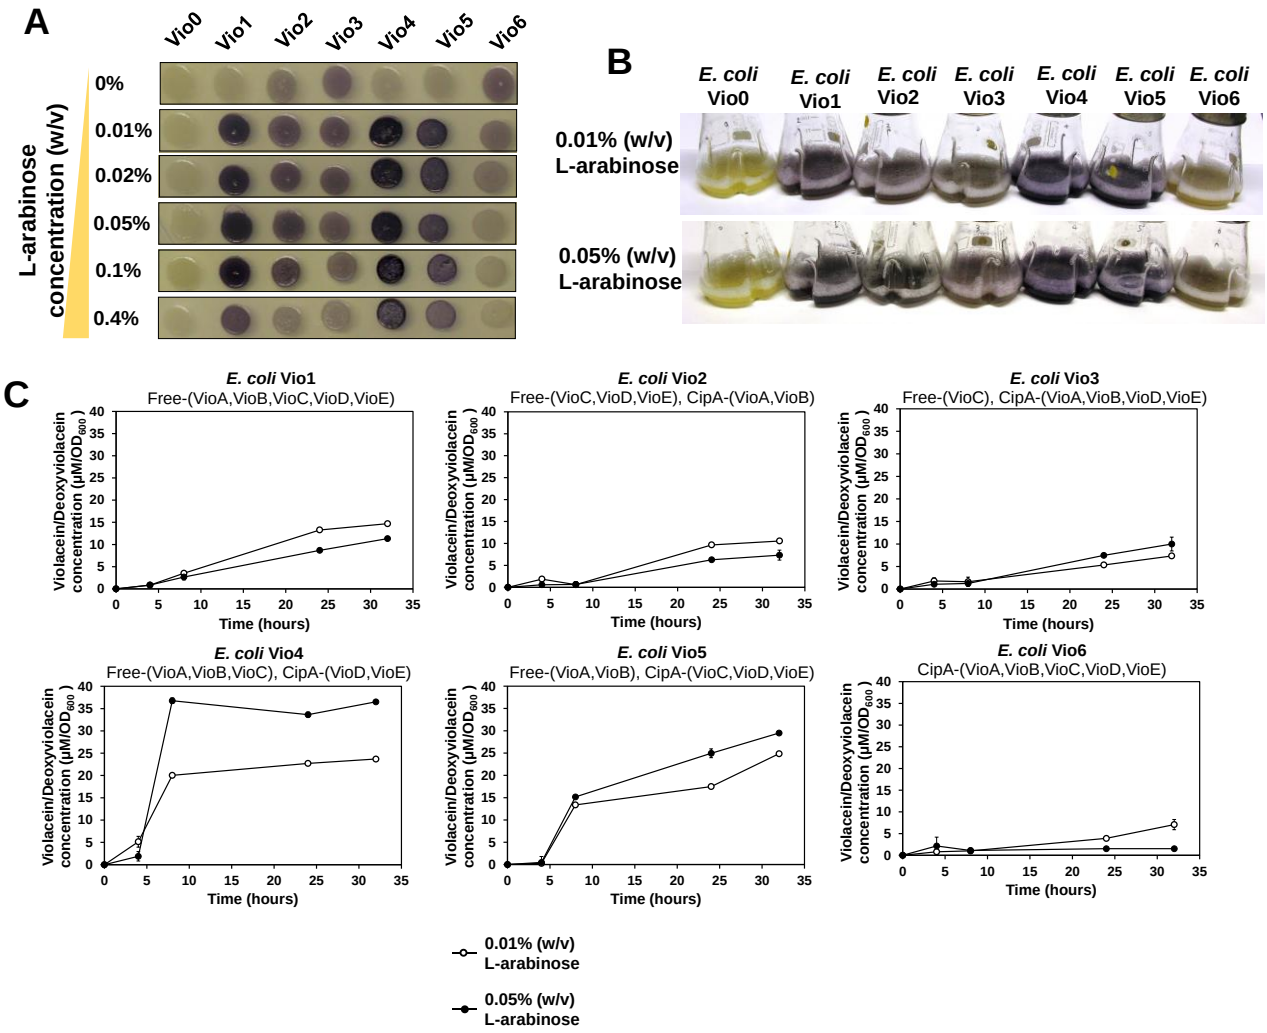

Figure 38: Batch cultivation of Vio strains for production of Violacein (A) Precultures of the engineered strains in Figure 37 were diluted with LB to an OD_{600} of 0.05 and dripped to LB plates containing indicated concentrations of L-arabinose and cultivated at 30°C overnight to stationary phase. The inducer concentration was selected according to the pigment accumulation. **(B)** Cultivation of *E. coli* Vio0 to *E. coli* Vio6 in LB medium supplemented with 0.01% (w/v) and 0.05% (w/v) L-arabinose for 32 h. Different levels of pigment accumulation were observed. **(C)**Time course of violacein and deoxyviolacein synthesis (mixture) in cultures of the engineered *E. coli* strains supplemented with 0.01% (w/v) or 0.05% (w/v) L-arabinose. Strain names and characteristics are given above the plots (see scheme in Figure 37).

Briefly, the final yields of violacein + deoxyviolacein were 11.3 µM/OD_{600} (Vio1: all Vio enzymes free), 7.3 µM/OD_{600} [Vio2: CipA-(VioA,VioB), all other enzymes free] 10.0 µM/OD_{600} [Vio3: CipA-(VioA,VioB,VioD,VioE); VioC free], 36.5 µM/OD_{600} [Vio4: CipA-(VioD,VioE), others free],

29.5 µM/OD_{600} [Vio5: CipA-(VioC,VioD,VioE); VioA and VioB free] and 1.5 µM/OD_{600} (Vio6: CipA-all Vio enzymes) (Figure 38C). These results show that productivity is very much improved in *E. coli* strains Vio4 and Vio5 in comparison to Vio1. However, *E. coli* Vio6 shows lower violacein and deoxyviolacein yield. This may be due to that the advantages by organizing Vio enzymes into into PCIs--increasing the intermediate concentration close to the enzyme active sites and facilitating the conversion of unstable metabolites--were counteracted by the disadvantages--decreasing the specific activities of the involved enzymes (as also shown in Figure 34 and 35).

The maximum rate of synthesis of violacein + deoxyviolacein for *E. coli* Vio1 was 0.4 µM/h per OD_{600}, it was 22.2-fold higher (8.7 µM/h per OD_{600}) and 8.8-fold higher (3.7 µM/h per OD_{600}) in strains *E. coli* Vio4 and *E. coli* Vio5, respectively.

In the next step, the ratios of violacein to deoxyviolacein were determined by HPLC (Figure 39). *E. coli* strains Vio3 and Vio6 had the lowest level of the by-product, but the overall yield was much lower than in *E. coli* strain Vio4 (Figure 38C). Overall, however, *E. coli* Vio5 was characterized to show the highest production of violacein, which was determined to be 183.2 µM (calculated from Figures 38C and 39B). In this strain VioC, VioD and VioE were organized into PCIs, while VioA and VioB were synthesized as free enzymes. Since VioE and VioD are, respectively, responsible for synthesis of the unstable intermediates PDVA and PVA, while VioC converts these into deoxyviolacein and violacein, respectively, encapsulation of the three enzymes clearly enhances both the overall productivity of the pathway - and selectivity for violacein.

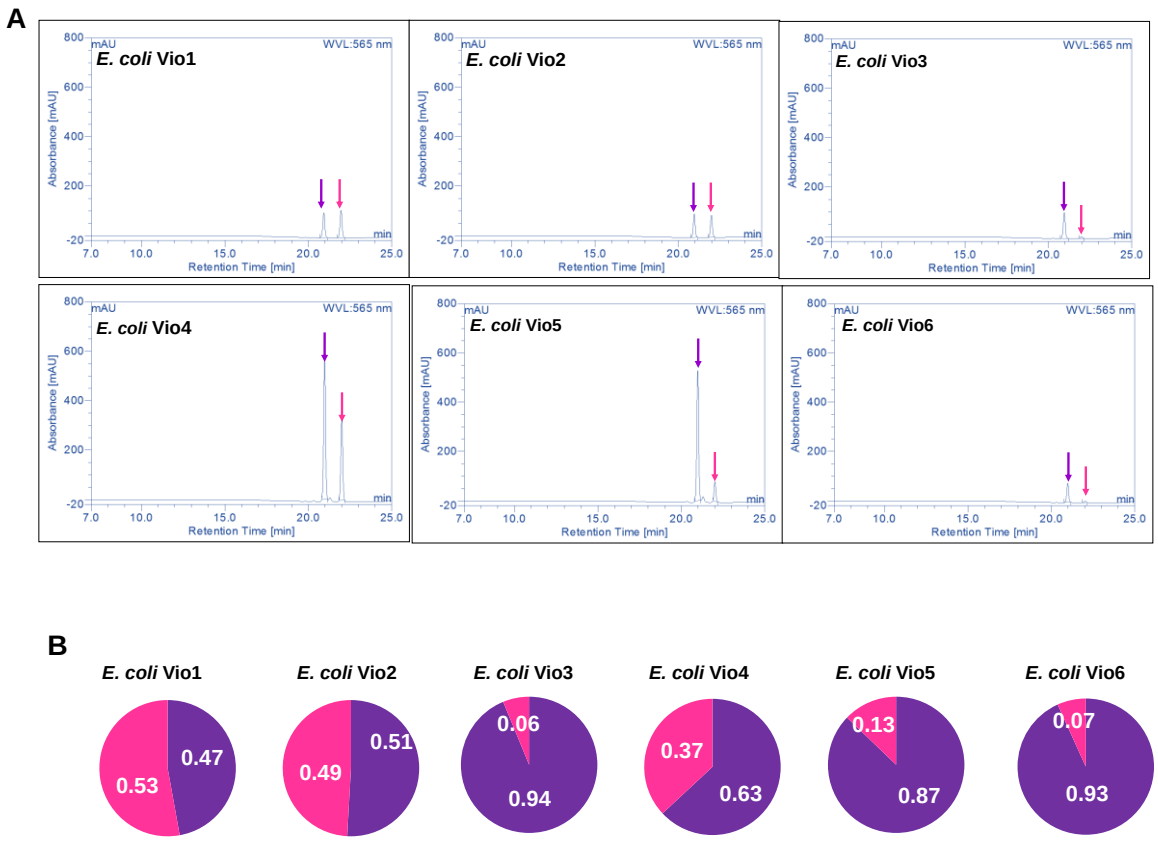

Figure 39: The ratios of violacein (violet) to deoxyviolacein (red) in the final product. (A) HPLC was performed as described in the chapter of Materials and Methods to analyse of the methanol-extracted violacein/deoxyviolacein mixtures produced by *E. coli* Vio1 to *E. coli* Vio6 strains. Fraction peaks of violacein (retention time 21 min) and deoxyviolacein (retention time 22 min) were marked with colored arrows. **(B)** Calaculated violacein and deoxyviolacein ratios in the methanol extracts of the listed six *E. coli* Vio strains

Additionally, the incorporation of Vio enzymes into PCIs was confirmed in strains *E. coli* Vio2-Vio6 by phase contrast microscopy and SDS-PAGE analysis of the insoluble fraction fater cell disruption (Figures 40A and 40B).

These results indicate that the VioA scaffold can organize multiple protein into PCIs *in vivo*. PCIs composed of multiple enzymes may play parts of the roles of organelles, which can bring related enzymes closer to each other and therefore enhance the metabolic flux to desired products.

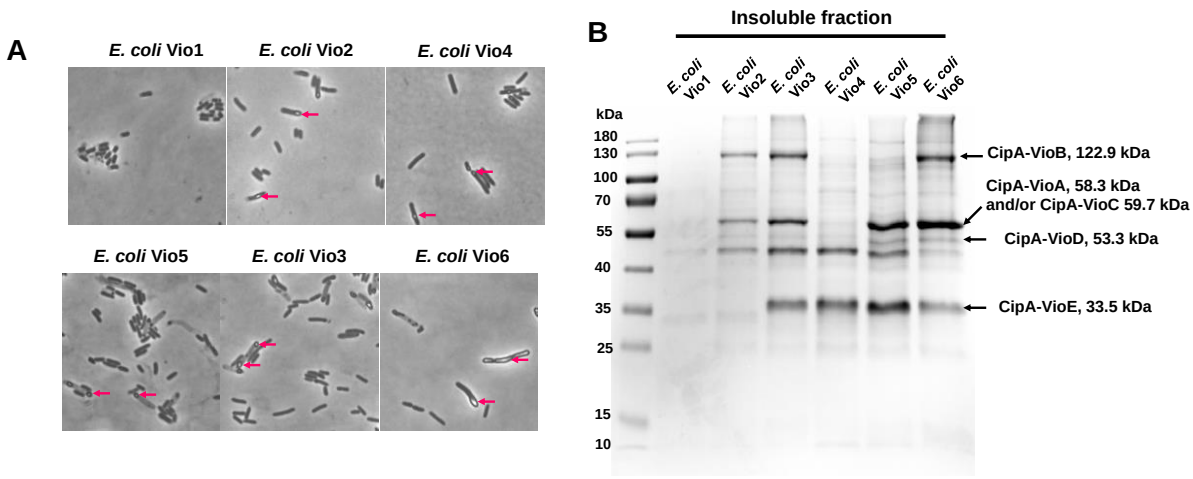

Figure 40: CipA scaffold organizes Vio enzymes into PCIs. (A) Vio enzymes were organized into PCIs (indicated by arrows) by CipA scaffold. Cells were collected at the 32 h time point and analyzed by microscope. Scale bar, 7.5 µm. **(B)** Cells of *E. coli* Vio1 to *E. coli* Vio6 were lysed after 32 h cultivation and insoluble fractions were collected and washed as described in the methods. Equal volumes (25 µL) of washed pellets were loaded on the SDS-PAGE. Gels were stained with Coomassie Brilliant Blue R-250. Arrows mark the Cip-Vio enzymes.

3.4.3 Truncation of Cip scaffolds

Despite native CipA/CipB have good performance in assembling proteins, they are generally much longer comparing to the commonly used protein tags, such as polyhistindine or FLAG octapeptiden tags, which have lengths ranging from six to around fifty amino acids. Therefore experiments were designed to investigate whether Cip scaffolds can be truncated while maintaining the scaffold functionality.

Firstly, the secondary structures of CipA and CipB were predicted with the PSIPRED software (Jones 1999). To protect secondary structures which may be important for the scaffold functionality, the truncation sites were chosen at their predicted loop regions (Figure 41A). The truncated versions of CipA and CipB were designed to be produced from the first methionine of the proteins to the amino acids at the indicated truncation sites (Figure 41A). The truncated Cip scaffolds were designated as CipA*1 [CipA(1-47)], CipA*2 [CipA(1-32)], CipA*3 [CipA(1-23)] and CipB*1 [CipB(1-59)], CipB*2 [CipB(1-33)], CipB*3 [CipB(1-17)], respectively.

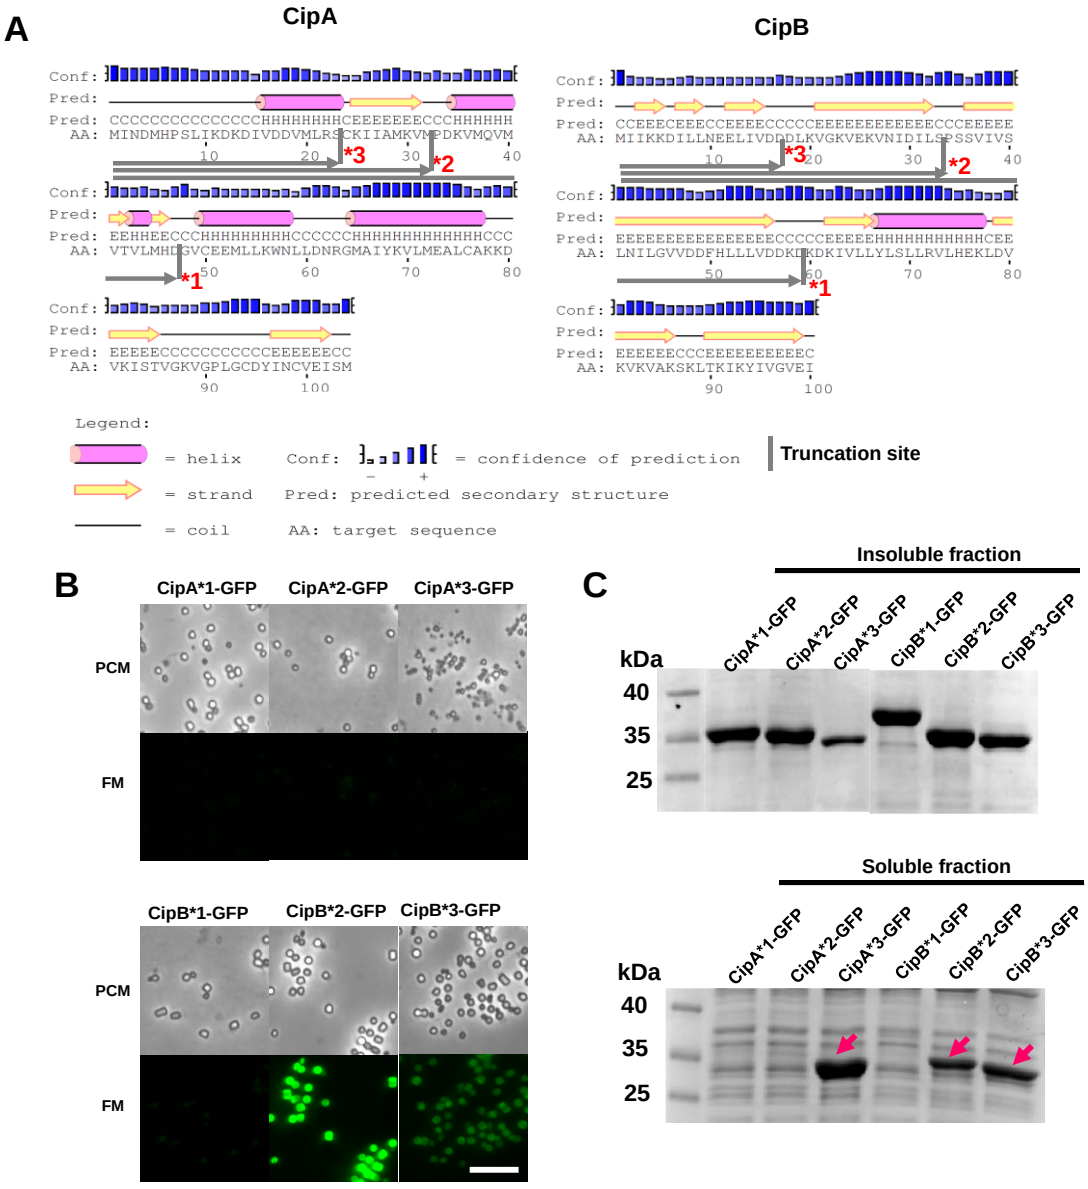

Figure 41: Truncated of Cip scaffolds bring GFP into PCIs. (A) Predicted secondary structures of CipA and CipB. Numbers with red asterisks demonstrate the truncation sites. The truncated scaffolds were produced from the first methionine until the amino acid at the indicated truncation sites. **(B)** Protein hybrids between CipA*1 [CipA(1-47)], CipA*2 [CipA(1-32)], CipA*3 [CipA(1-23)] , CipB*1 [CipB(1-59)], CipB*2 [CipB(1-33)] or CipB*3 [CipB(1-17)] and GFP were separately produced in *E. coli* at 37°C as described in Figure 27. GFP PCIs were isolated as described in (C) and used for microscopy. PCM, phase contrast microscopy; FM, fluorescence microscopy. Scale bar, 7.5 µm. **(C)** Cell producing GFP PCIs were lysed and soluble fractions and insoluble fractions were subsequently separated as described in Figure 7. The insoluble fractions were washed three times and resuspended with Na-phosphate buffer to the same volume of soluble fractions. Equal volume (25 µL) of soluble fractions and insoluble fractions were loaded on SDS-gel, which was stained with Coomassie Brilliant Blue R-250. Arrows mark the bands composed of CipA3*-GFP CipB*2-GFP and CipB*3-GFP, which were detected in both soluble and insoluble fractions.

Protein hybrids between GFP and truncated Cip scaffolds were produced in *E. coli* at 37°C as described in Figure 27. The PCIs were subsequently isolated as described in Figure 7 and inspected under microscope. All the truncated vriants of Cip scaffolds, can support the assembly of GFP into PCIs, even when two of them were truncated to lengths of about 20 amino acids (Figure 41B).

However, the PCIs assembled by the truncated CipB scaffold show very distinct fluorescence intensities, while PCIs assembled by the truncated CipA scaffolds show less differences (Figure 41B). Such kind of difference should be caused by the distinct secondary structurs of CipA and CipB. Both CipB and GFP are rich of β-sheet secondary structures, while CipA mainly composes of α-helix (Yang, Moss et al. 1996). When CipB was truncated, originial interaction between the β-sheets of wild type CipB might be replaced by the intermolecular interaction between the β-sheets of truncated variants of CipB and that of GFP, which in turns, affects the GFP structure and its fluorescence properties.

Moreover, there were large proportions of CipA*3-GFP, CipB*2-GFP and CipB*3-GFP detected in the soluble fraction via SDS-PAGE, indicating the lower assembly efficiencies of the Cip scaffold variants (Figure 41C).

4 Discussion

4.1 The evolutionary analysis of KdpD proteins

4.1.1 Classification of KdpD proteins

Current knowledge on KdpD proteins are mainly based on the research on the Kdp systems of four species: *E. coli*, *S. aureus*, *Synechocystis* sp. strain PCC 6803 and *Anabaena* sp. strain L-31. Since KdpD protein was firstly known from *E. coli* as a histidine kinase (Walderhaug, Polarek et al. 1992), the KdpD proteins identified later from the two cyanobacterial species were therefore named as “truncated” KdpD, due to the missing transmembrane domain and the essential elements of kinase, HiskA and HATPase_c domains. However, it is a bit arbitrary to speculate that KdpD protein ought to be a “*kinase*” and the shorter version of KdpD proteins were just “truncated” (Importantly, in the current study, the “KdpD protein” is defined by the presence of KdpD domain). Moreover, it was demonstrated that the domain architectures of KdpD domain-containing proteins are rather diverse (Figure 11) and, therefore should extend beyond the previously reported “full-length KdpD” of *E. coli* and “truncated KdpD” of *Cyanobacteria* (Ballal and Apte 2005, Ballal, Bramkamp et al. 2005, Ballal, Basu et al. 2007, Nanatani, Shijuku et al. 2015).

Based on the analysis of the sequences of 661 KdpD domain-containing proteins (“KdpD proteins”) described above, they were classified into three groups (Figure 11). The *kinase* KdpD comprise the largest group, with 449 proteins, followed by the *non-kinase* KdpD (206 proteins). The *dysfunctional kinase* group is a very small group with only 6 representatives, and its domain architecture is quite similar to that of the *kinase* KdpD (Figure 11A).

4.1.2 Function of KdpD proteins

Regardless the domain compositions, coordinated distribution of KdpD and KdpA proteins was found in a broad range of bacterial species (Figure 9). This finding suggests the function of KdpD protein is highly related to the Kdp system. However, there are two inevitable questions

regarding to the exact function of KdpD proteins: **(i)** How does *non-kinase* KdpD performs its regulatory role without any signal output domain of either TCS (HisKA and HATPase_c domains) or that of one-component system (*e.g.* HTH domain which can potentially binds to DNA sequences), especially when all the knowledge regarding to the regulation of the Kdp system is transcriptional regulation; **(ii)** Why are bacterial species equipped with KdpD proteins with different domain architectures (Figure 13A).

To answer question one, the assumption is that the *non-kinase* KdpD is an auxiliary protein to the alternative HK^{K+}/RR^{K+}, while KdpD-Usp domain of *kinase* KdpD is an "auxiliary part". There are several evidences in favor of this assumption.

Firstly, according to some reports, the *non-kinase* KdpD is not really essential for the expression of *kdp* operon in response to K^+, at least in two cyanobacterial species (Figure 3) (Ballal and Apte 2008, Nanatani, Shijuku et al. 2015).

Secondly, there are several reports on the "auxiliary" function of the KdpD and/or Usp domains. **(i)** *E. coli* KdpD domain was report to contain a modified of 'Walker-type' ATP-binding site which is able to stabilize the complex formed between the phosphorylated KdpE dimer and the DNA (Jung and Altendorf 1998, Heermann, Altendorf et al. 2003); **(ii)** The Usp domain associated with KdpD proteins is known to mediate different functions in several bacteria. For example, the Usp domain in *E. coli* KdpD is recognized by UspC, which serves a scaffolding function under salt stress (Heermann, Weber et al. 2009). In *Staphylococcus aureus* the Usp domain in KdpD binds c-di-AMP (Moscoso, Schramke et al. 2016).

All these reported functions are based on the presence of the histidine kinase module (HiskA and HATPase_c domains).

To answer question two, it was attempted to identify some relations between the domain architecture of KdpD proteins and the phenotypes, lifestyles or the habitats of host cells, *e.g*. free-living vs. host-associated, potassium-rich vs. potassium-poor habitats, and pathogens vs.

nonpathogens. However, there is no obvious correlation found (Table 6). Different bacterial species also show specific preferences to *kinase* or *non-kinase* KdpD, which further complicates the question (Figure 13C). All in all, there was no evidence detected that the *kinase* and *non-kinase* KdpD are more profitable to the host cells than the other.

Table 6: No correlation was found between the domain architectures of KdpD proteins and host lifestyles

Species	KdpD architecture (form N to C terminus)	Habitat	Virulence/ Pathogenicity
Myxococcus xanthus	KdpD-Usp	soil, decaying plant	no
Synechocystis sp. PCC6803		freshwater, both heterotrophic and photosynthetic	no
Bacteroides fragilis		normal flora of the human colon	causing anaerobic infections
Propionibacterium acnes HL060PA1	KdpD-Usp-DUF4118-X-HiskA-HATPase	commensal of human skin	causing inflammation, acne vulgaris
Streptomyces coelicolor A3(2)		soil, metabolizing other organism's remains	no
Mycobacterium tuberculosis		intracellular pathogens	causing tuberculosis
Escherichia coli K-12	KdpD-Usp-DUF4118-GAF-HiskA-HATPase	commonly found in the lower intestine of warm-blooded organisms	no
Pseudomonas putida F1		found in most soil and water habitats	no
Burkholderia mallei savp1		soil and associating with animals	human and animal pathogen causing glanders

4.1.3 DUF4118 domain containing proteins

The DUF4118 domain, comprising the four transmembrane helices, is crucial for stimulus perception by KdpD, as it includes the binding site for external K^+ in *E. coli* (Zimmann, Steinbrugge et al. 2007, Schramke, Tostevin et al. 2016). Moreover, the DUF4118 domain is certainly important for the function of *kinase* KdpD, since 413 out of 449 *kinase* KdpD contain this domain (Figure 13A). From another angle, there are about ~50% of DUF4118 domains not incorporated into KdpD proteins (Table 4 and Data set-sheet 6). Although DUF4118 domain-containing HK are encoded in the genomes of cyanobacterial species, these bacteria

recruits, nevertheless, 4TM(2TM)-HK^{K+} to regulate the expression of the *kdp* operon (Figure 17).

DUF4118 domain is more versatile than the KdpD domain, and should participate in other signaling activities. For example, some DUF4118 domains were found to be connected to class III nucleotidyl cyclase domains (nucleotidyl_cyc_III superfamily) or phosphohydrolases with a conserved 'HD' motif (HDc) and might play a role in second messenger metabolism (Table 4 and Data set-sheet 6).

4.1.4 Multiple factors contribute to the evolution of KdpD proteins

The evolution of KdpD proteins is a very complicate process. It involves many kinds of evolutionary events such as gene loss or gene drift, duplication, recombination, HGT and nucleotide mutations. Moreover, KdpD proteins do not have uniform evolution scenarios among the investigated bacterial species.

(i) *kdpD* and *kdpA* are undergoing widespread gene drift or gene loss events. The KdpD and KdpA proteins have been detected with widespread existence in bacterial phyla/group [(Data set-sheet 2, 18 out 26 bacterial phyla/group have detected KdpD]. Some bacterial phyla/group have no detected KdpD. This is likely due to their low proteome sampling number in the selected RFP (Data set-sheet 2). However, KdpA and KdpD protein show very low prevalence in the three domains of life (Figure 11). On average about 20% bacterial species have KdpD and KdpA (Figure 11C). These findings suggest that the KdpD and KdpA proteins are undergoing gene drift or gene loss events (see also the following 4.1.5, discussion on the Kdp system of *Firmicutes*)

(ii) Lineage-specific evolution events of KdpD proteins

Lineage-specific evolution events of KdpD proteins have been shown on the following aspects.

Firstly, different bacterial phyla or groups have quite distinct prevalences of KdpD proteins (Figure 11B).

Secondly, different bacterial phyla or groups have different proportions of *kinase*, *dysfunctional kinase* and *non-kinase* KdpD (Figure 11C).

Thirdly, domain architecture of the KdpD proteins are not uniform among the bacteria phyla/group (Figure 13B).

Fourthly, intensive KdpD duplications were detected (including protein duplication and domain duplication) in *Firmicutes* and *Actinobacteria*, but not detected in the other bacterial groups/phyla. The KdpD protein duplication, as *kinase*, occurred after the divergence of *Actinobacteria*, because as observed, the duplicated proteins are clustering into one group (Figures 12 and A2). While KdpD domain duplication in *non-kinase* KdpD proteins should also have occurred after the divergence of *Firmicutes*, because almost all the KdpD with the domain architecture KdpD-Usp-KdpD-Usp were detected in this phylum. Such kind of special structure should be generated via domain duplication of KdpD-Usp.

Fifthly, HGT involves in the evolution of KdpD protein. In addition to the archaeal KdpD (see section 3.1.1), *Firmicutes* KdpD proteins do not form unique phyletic groups (Figure 12) on the protein tree. This should be due to either *kdpD* gene paralogs or HGT. The latter one may be more approaching to the truth. This is because one group of *Firmicutes* KdpD proteins that have close phylogenic relations with *Proteobacteria* KdpD, also show quite similar domain architectures to *Proteobacteria* KdpD (see Figure A2).

(iii) Domain shuffling/recombination mediate the interconversion between *kinase* and *non-kinase* KdpD.

KdpD protein evolution is not only a matter of KdpD domain itself. It is also involves the *DUF4118 domain protein*. As shown in 3.1.4, domain shuffling between Usp and DUF4118

domains clearly supports the interconversion between *kinase* and *non-kinase* KdpD. Focusing on the interconversion of *non-kinase* and *kinase kdpD* genes, one can envisage **(i)** the transformation of a *kinase kdpD* into a *non-kinase kdpD* by gene fission or **(ii)** the converse transition from *non-kinase* to *kinase kdpD* by recombination with a *hk*$^{K+}$ sequence (gene fusion).

Several lines of evidence argue in favor of the predominance of the second route. Firstly, various types of *hk*$^{K+}$ were detected in the genomic vicinity of *non-kinase kdpD* genes, which encode, for example, HK^{K+} with a HAMP and/or a PAS domain [2TM-HAMP-PAS(X)-HK^{K+}] (Figure 15). But corresponding *kinase* KdpD that contained a HAMP or PAS domain were not found (Figure 11A), which could potentially be converted into a *non-kinase* KdpD and HK^{K+} with HAMP and/or PAS domain by fission of its encoding gene. Sencondly, *non-kinase kdpD* genes are always located adjacent to *kdp* operons, but the orientations of *hk*$^{K+}$ and *rr*$^{K+}$ genes and their positions with respect to *non-kinase kdpD* and *kdp* operons vary in different species (Figure A3). This finding suggests that these *hk*$^{K+}$ and *rr*$^{K+}$ do not share the same operon as the *E. coli kdpDE* and may be separately derived from different *hk/rr* pairs via gene duplication and divergence, but not from the fission of *kinase kdpD* genes. Furthermore, as reported by Kummerfeld *et al.*, during the evolution of multidomain proteins, gene fusion events occur four times more often than gene fission events (Kummerfeld and Teichmann 2005).

The results described in 3.1.5 reveal also that three KdpD domains have evolved under strong purifying selection, which demonstrates that the corresponding gene is essential as non-synonymous mutations are rapidly eliminated. In addition, there is clear evidence for several instances of positive selection on branches of the phylogenetic tree where switches from *non-kinase* to *kinase* (or the reverse) must have occurred. Three of the four branches under positive selection are branches leading to *kinase* KdpD (Figure 14), which shows that the switch has occurred in evolution, and consequently this gain of function can confer a selective advantage for bacteria cells.

4.1.5 The most special case--Firmicutes Kdp system

In comparison with other major bacterial phyla (Proteobacteria and *Actinobacteria*), the *Firmicutes* exhibits the greatest diversity of KdpD protein architectures (Figure 11B) but the species of *Firmicutes* are less likely to have KdpD- and KdpA domain-containing proteins (Figure 9B). This phylum has almost equal proportions of the *kinase* and *non-kinase* KdpD proteins (Figure 11C). All these findings indicate that the KdpD proteins of *Firmicutes* have followed a very distinct evolutionary trajectory, and imply that the Kdp-based system of potassium may play a less significant role in this phylum.

For example, it has been reported that deletion of the Kdp transporter encoding operon or the gene of *non-kinase* KdpD protein in *Bacillus cereus* does not affect cell growth under potassium-limited conditions (Mellegard, Kovacs et al. 2011). Moreover, the genome of *B. subtilis* encodes neither a Kdp potassium transporter nor KdpD proteins. In contrast, two Ktr potassium transport systems, KtrAB and KtrCD, have been identified in this species. The membrane-integrated KtrB and KtrD in *B. subtilis*, as well as membrane subunits of the two Trk systems in *E. coli* (TrkH and TrkG), all belong to the TrkH superfamily. They have been detected by the HMMER 3.0 with the HMM model of the TrkH domain and are listed (in green) in Data set-sheet 5. With regard to their affinities for K^+, KtrAB and KtrCD have K_m values of 1 mM and 10 mM (Holtmann, Bakker et al. 2003), while the two Trk systems (Figure 1) in *E. coli* have K_m values of 1 mM or less (Schlosser, Meldorf et al. 1995). This results indicates that *B. subtilis*, as a typical representative of the *Firmicutes*, either has less need for potassium or uses other strategies, such as sporulation or biofilm formation, to cope with K^+ limitation (Grau, de Ona et al. 2015).

4.1.6 Alternative HK^{K+}/RR^{K+} and the *B. fragilis* Kdp system

As have discussed above, the core regulator of the Kdp system should be the kinase module of *kinase* KdpD and the cognate RR (for Kdp system equipped with *kinase* KdpD) or the

HK^{K+}/RR^{K+} (for *Kdp* system equipped with *non-kinase* KdpD). According to this assumption, the genomic neighborhoods of Kdp systems equipped with *non-kinase* KdpD were compared to each other, and in the selected regions some operons which may potentially encode the HK^{K+}/RR^{K+} (Data set-sheet 8 and Figure A3) were found. Their domain architectures were predicted with CDD v3.14 and the transmembrane domain with TMHMM 2.0 (Krogh, Larsson et al. 2001) and DAS (Cserzo, Wallin et al. 1997) (see 2.1.4). The HK^{K+}/RR^{K+} pairs were classified into three groups (Figure 15).

Among the three types of alternative HK^{K+}/RR^{K+}, the third pair (Figure 15) is mostly interesting, which was found mainly in some *Deltaproteobacteria* and *Bacteroidetes*. This is because the RR^{K+} was predicted to be σ^{54} dependent transcriptional activator and the HK^{K+} was predicted to have two transmembrane helices (DUF4118 domain has four transmembrane helices) (Figures 15, A3A, and Data set-sheet 8). The σ^{54} factor differs in sequence and structure from that of σ^{70} family sigma factors (Lonetto, Gribskov et al. 1992, Gruber and Gross 2003).

The *B. fragilis* was chosen as the object to study on the σ^{54} -dependent *kdp* operon, because **(i)** It associates mutually with humans and other mammals, as an opportunistic pathogen, while Kdp system has been found to integrate K^+ homeostasis and virulence (Freeman, Dorus et al. 2013); **(ii)** It lives in a potassium rich niche, but preserves the low potassium response system.

Here, preliminary studies were performed to characterize the *B. fragilis* Kdp system. The expression of *B. fragilis kdp* operon was confirmed to be in response to low K^+ (Figure 16). The K^+ limitation faced by this bacterium may be caused by the formation of biofilms, which is mainly made of multiple layers of *Firmicutes*, *Bacteroidetes*, *Proteobacteria* in the large intestine (Jandhyala, Talukdar et al. 2015, Johnson, Dejea et al. 2015). *B. fragilis* Kdp system recruits σ^{54} factor transcriptional activator as the RR^{K+} may indicate tighter transcriptional regulation. *E. coli* reporter assay gives some evidences that the predicted HK^{K+}/RR^{K+} should invovle in the regulation of *B. fragilis kdp* operon, because the expression of hk^{K+}/rr^{K+} increase

the expression level of the reporter gene *lac*Z (Figure 18). But more straightforward experiments like deletion of related genes (see Figure 16) are certainly required.

4.2 Structural analysis of KdpD proteins

There are generally three common methods which have been used for the determination of protein structures.

(i) Nuclear magnetic resonance (NMR) spectroscopy can determine the structure of small proteins in the solutions or that of membrane proteins in lipid bilayers or detergent micelles (as described above for the structure determination of the DUF4118 domain). Analyzing protein structure with NMR does not require protein crystallization and could detect the conformational changes of proteins. However, application of NMR is limited by upper molecular size (protein molecules should be smaller than 30 kDa. Membrane protein dissolved in detergent micelles should be even smaller) and low resolutions.

(ii) Reconstruction of the protein structure of protein complexes with single-particle cryo-EM has recently attracted very intensive attention. It is considered to be a very promising method for protein structural analysis (Vinothkumar 2015, Doerr 2016, Skiniotis and Southworth 2016, Frank 2017). In the past few years, this method has been being steadily improved. It enables successful reconstruction of the structure of enzyme complexes, virus particles, ribosomes, ion channels with “large, fragile, or flexible structures” to near-atomic resolution (Scheiner 2015). Protein samples ould be treated with negative staining or cryogenic freezing, and as designated by the name, no protein crystallizition is needed. However, careful preparation of samples is required to keep them homogeneous in solutions. Moreover, the size of the molecule should be larger than 150 kDa (Thompson, Walker et al. 2016).

Smaller membrane protein may be embedded into liposomes or nanodiscs. The later one is a self-assembled discoidal particle composed of lipid bilayers surrounded with membrane

protein scaffold (MSP) as the belts. Nanodiscs are soluble in aqueous solutions, with a diameter of 8–16 nm (depends on the lenth of MSP and the inserted protein size) and therefore can afford the native environment for the membrane proteins and assistant particle recognition during cryo-EM (Denisov and Sligar 2016). Assembly of the nanodiscs is an automatic process (Bayburt, Grinkova et al. 2002, Denisov, Grinkova et al. 2004).

(ii) X-ray crystallography has been the most prevalent strategy of protein structure determination. It requires protein crystallization, which is always a big obstacle, especially for membrane protein. Proteins integrated into the membrane have very hydrophobic surfaces and very flexible conformations (Carpenter, Beis et al. 2008). There are actually challenges at almost every step before coming to the crystallization of membrane proteins, such as low production, instability, aggregation. Membrane proteins can be extracted from the membrane lipid with detergent into aqueous solutions for the purpose of crystallization. Meanwhile, there are also other careful designs to promote the crystallization of membrane proteins, such as fusing soluble protein to stabilize transmembrane domain loop and increase solubility (Chun, Thompson et al. 2012).

The biggest obstacle of crystallizing KdpD lays at the hydrophobic feature of these proteins. On one hand, the DUF4118 domain is entirely embedded into the lipid bilayers. On the other hand the natively occurring *non-kinase* KdpD composed of KdpD and Usp domains, even containing no transmembrane helix, shows high affinity to the cytoplasmic membrane (Figure 22). It has also been shown that the KdpD-Usp domain can make the GFP protein approach to the cytoplasmic membrane (Maier, Hubich et al. 2008) .

The topology of the *kinase* KdpD was speculated in Figure 42 (Jung, Tjaden et al. 1997). The stress signal acting on membrane may be perceived via tight interaction between KdpD-Usp and the cell membrane. Crystallization of proteins does not only requires the sample to be pure but also must be homogenous and stable. The hydrophobicity of KdpD proteins makes their

molecules very aggregation-prone, and accordingly the precipitation during crystallization setups of KdpD-R511Q. Artificial design was aimed to promote the asymmetry of *kinase* KdpD via inserting the WrbA protein to the first periplasm loop of the DUF4118 domain. It, nevertheless, causes the accumulation of truncated proteins (Figure 21). The introduction of WrbA may interrupt the insertion of the transmembrane helices and therefore causes premature translation termination. All in all, crystallography does not seem to be the proper way to resolve the KdpD structure.

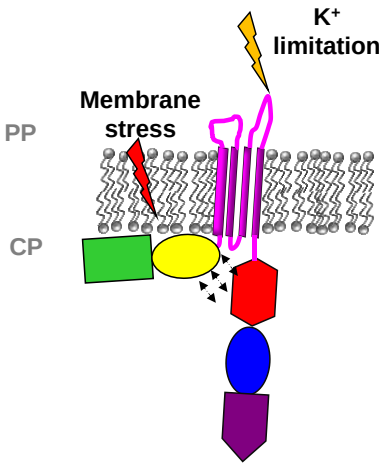

Figure 42: Assumed topology of the *kinase* KdpD basing on its hydrophobicity. KdpD and Usp domains have very high affinity to the cytoplasmic membranes. The interaction between KdpD-Usp and lipid bilayer may make the convergence of membrane stress to the kinase module. While the secondary periplasmic loop is known for sening K^+ limitation. PP: periplasm, CP: cytoplasm.

Single particle cryo-EM seems to be a quite promising practice to solve the structure of *kinase* KdpD. The functional form of *kinase* KdpD is a dimer with a molecular weight of ~200 kDa (Heermann, Altendorf et al. 1998), while the lower limit protein (complexes) size of protein cryo-EM at current stage is about 150 kDa (Thompson, Walker et al. 2016). If the dimer could be successfully assembled into nanodiscs, there is good reason to expect that the structure of *kinase* KdpD could be solved by cryo-EM. Since time was limited, only very preliminary trials were performed to assemble KdpD protein into nanodiscs (Figure 23). Further experiments are required to check the assembly is successful. Moreover, intensive optimization of the KdpD,

MSP and lipid stoichiometric ratios is certainly required, to make sure that the samples are homogeneous.

4.3 The biotechnological application of Cip scaffolds

4.3.1 Protein subcellular structures

Proteins can be natively organized *in vivo* into various structures with different biological functions. Their formation are under tight regulations of cells' demands. For example in some autotrophic bacteria like *Phormidium uncinatum* and *Halothiobacillus neapolitanus*, their predominant enzymes catalyzing carbon fixation --ribulose-1,5-biphosphate carboxylase and the oxygenase -- can form polyhedral protein inclusions, known as carboxysome (Tsai, Sawaya et al. 2007, Yeates, Kerfeld et al. 2008). In order to get buoyancy, some planktonic microorganism produce proteins such as GvpA and GvpC which can assemble together into gas vesicles (Pfeifer 2012). Cry and Cyt proteins of *Bacillus thuringiensis* can assemble into parasporal crystalline inclusion, commonly known as Bt crystals, which have pesticidal activities (Agaisse and Lereclus 1995, Schnepf, Crickmore et al. 1998, Parker and Feil 2005, Bravo, Gill et al. 2007).

4.3.2 The CipA and CipB proteins

CipA and CipB are short proteins with respectively 104 and 100 amino acids and they also assemble into two distinct types of crystalline inclusions with polyhedral configurations in the primary cells of entomopathogenic *Photorhabdus luminescens*. The formation of CipA and CipB crystalline inclusion production is tightly regulated by the native host cell (Bintrim and Ensign 1998, Bowen and Ensign 2001, Heermann and Fuchs 2008). Besides, the sister genus of *Photorhabdus*, *Xenorhabdus nematophila* also produce two types of crystalline inclusions named IP1 (methionine-rich PixA inclusion with 185 amino acids and encoded by *pixA*) and IP2 (encoded by uncharacterized gene) (Couche and Gregson 1987). The common feature of CipA, CipB and PixA is that they all have high percentage of (~50%) hydrophobic amino acids.

In contrast to the Bt crystals and the carboxysome, the functions of crystalline inclusions produced in *Photorhabdus* and *Xenorhabdus* remain ambiguous (Goetsch, Owen et al. 2006, Goodrich-Blair and Clarke 2007).

The formation of CipA, CipB, and PixA might be also driven by hydrophobic amino acid, but this is different from the formation of protein inclusion bodies. The formation of the PCIs in the native producer *P. luminescens* are tightly regulated, while the formation of protein inclusion bodies are generally out of the control of the producer. As described, at lower temperature of 20 °C, the organization of CipA-GFP and CipB-GFP as non-refractile protein complexes were still visibile (Figure 28), and they can be disassembled by mechanical cell disruption into soluble proteins (Figure 32). This result suggests the proteins are correctly folded and the organization process of the proteins is not caused by the mis-folding of the proteins, but due to the scaffold function of CipA and CipB. Additionally, Congo Red absorption spectra shift assay has shown that the LacZ PCIs do not have the enriched β-sheet structure, which is commonly found in protein inclusion bodies.

4.3.3 *In vitro* application of Cip scaffolds

By hybridizing the reporter GFP to Cip, it was found that the assembled complexes could be compact crystalline inclusion or loose textures (Figures 27 and 28). The isolation of the PCIs complexes is effortless and can be finished within 2-3 hours (Figures 7 and 43).

Genearlly, it is important to improve the solubility of recombinant proteins in some applications. On the opposite, there are also significant efforts being spent on decreasing the solubility of a protein, like immobilizing enzymes, which also has very practical importance such as enhancing stability of the enzyme during catalysis and simplifying the recovery & reusing of the enzymes at the downstream processing (Mohamad, Marzuki et al. 2015). Cip scaffolds can immbolize enzymes in to PCIs. Moreover this process can be carried out *in vivo* by the cells. As have been shown that CipA-LacZ and CipB-LacZ PCIs are more thermal resistant that the

soluble His-LacZ (Figure 34). Moreover, these PCIs can be recovered by centrifugation for recycling. These advantages are very useful for practical applications.

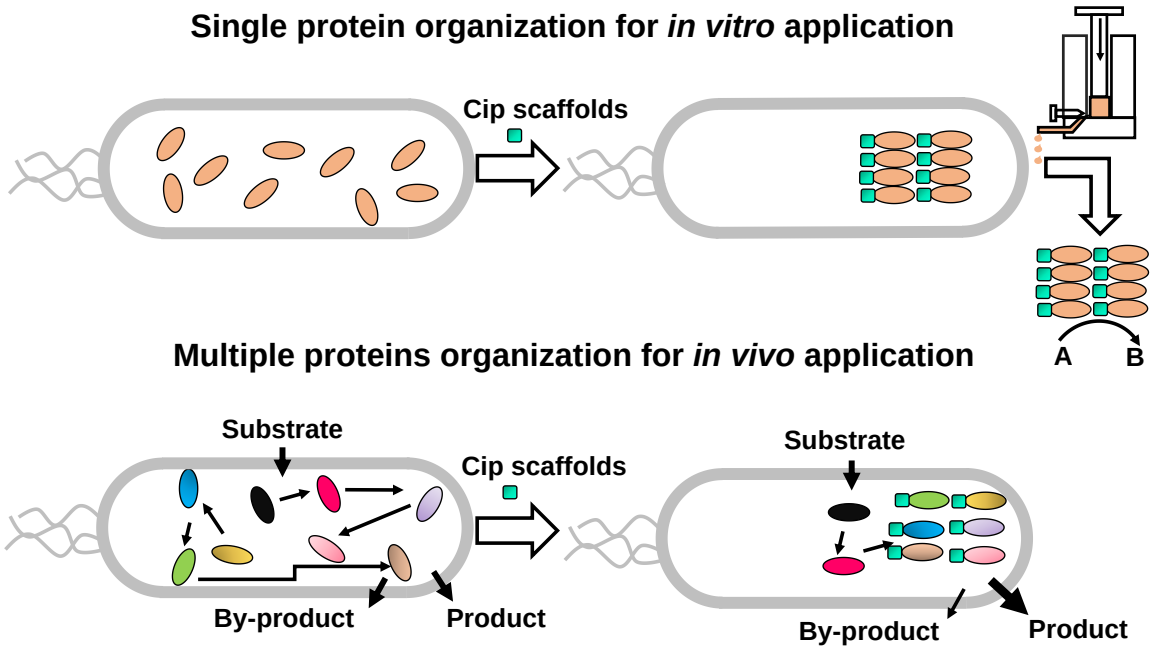

Figure 43: Schematic of *in vitro* and *in vivo* applications of Cip scaffolds. For *in vitro* applications PCIs can be isolated easily after cell disruptions. For *in vivo* applications multiple enzymes could be brought closer to each to promote the rapid conversion of unstable intermediates and therefore increase the production of desired products.

4.3.4 *In vivo* application of Cip scaffolds

For *in vivo* applications, the use of Cip scaffolds enables flexible organization of multiple enzymes into complexes (Figure 43). Such kind of complexes are not aimed for isolation and *in vitro* catalysis application. Therefore, they do not have to be in the PCIs state (see the GFP complexes form at 20 ºC, Figure 28). The multiple enzyme complexes may be considered as a kind of no-membrane-bound organelles, which can bring multiple enzymes spatically closer to each other. This can help to speed up the conversion of unstable intermediates and avoid the unwanted diffusion of toxic metabolites (Dueber, Wu et al. 2009, Yadav, De Mey et al. 2012, Proschel, Detsch et al. 2015).

As shown here for violacein biosynthesis, bringing the multiple Vio enzymes together via CipA has improved the overall yield of the desired product and reduced side-product accumulation (Figures 38 and 39). This holds significant importance in the field of synthetic biology and metabolic engineering.

Cip scaffolds can organize proteins into PCIs with versatile applications. The resulting protein complexes can **(i)** retain the original enzyme activities, **(ii)** remain stable during product synthesis, **(iii)** and can be easily isolated for *in vitro* applications or be capable of organizing multiple proteins for *in vivo* usages.

5 Summary

KdpD/KdpE is a pair of histidine kinase/response regulator (HK/RR) systems sensing K^+ limitation and mediating intracellular K^+ homeostasis. The KdpD of *Escherichia coli* is a multi-domain membrane protein with an unusual cytosolic N-terminal region, which contains a unique KdpD domain. KdpE controls expression of the high-affinity K^+ uptake system KdpFABC. In this work, all proteins containing the special KdpD domain were collected as KdpD proteins. According to the domain architectures, KdpD proteins were classified into *kinase*, *non-kinase* and *dysfunctional kinase*, which do not distribute uniformly among bacterial phyla. Lineage-specific evolutionary events such as *kdpD* gene duplication and intensive horizontal gene transfer were detected. Besides, domain shuffling and selective pressure on nucleotide sequences were found to promote the interconversion between the *kinase* and *non-kinase* KdpD.

The investigation of the genomic contexts of *non-kinase kdpD* genes in different bacteria revealed several types of alternative HK and RR, designated as alternative HK^{K+}/ RR^{K+}, which might regulate induction of the *kdp* operon in response to K^+ limitation. Some of the alternative RR^{K+} were predicted to be σ^{54}-dependent transcriptional activators. To confirm the prediction, the K^+ responsive elements of the Kdp system of *Bacteroides fragilis* were investigated.

Several approaches were used to determine the structure of *kinase* or *non-kinase* KdpD proteins via crystallography, but no promising results were obtained. A protocol was established to incorporate the *kinase* KdpD into nanodiscs as prerequisite for single particle cryo-EM.

CipA and CipB are two small proteins that form protein crystalline inclusions (PCIs) in the cytoplasm of *Photorhabdus luminescens*. CipA and CipB were originally developed as Cip scaffolds to organize proteins, such as *non-kinase* KdpD, into PCIs for the purpose of crystallography. However, most of the obtained PCIs did not show a diffraction signal.

Therefore, the biotechnological application potential of Cip scaffolds was evaluated in *E. coli*. On the one hand proteins such as LacZ, could be incorporated into PCIs and readily isolated for *in vitro* applications, because the PCIs are insoluble in water and resistant to high temperature. On the other hand, Cip scaffolds could organize multiple enzymes into functional complexes *in vivo* and are therefore useful tools for metabolic engineering, as revealed by improving the production of violacein.

6 Zusammenfassung

Das aus Histidinkinase und Antwortregulator (histidine kinase HK/respones regulator RR) bestehende Zweikomponentensystem KdpD/KdpE reagiert auf K+ Limitierung und vermittelt durch eine Signaltransduktion eine intrazelluläre K+ Homöostase. Das *Escherichia coli* KdpD ist ein Multidomänen-Membranprotein mit einer ungewöhnlichen N-terminalen Region, die eine besondere KdpD Domäne enthält. KdpE reguliert die Expression des hochaffinen K+ Aufnahmesystems KdpFABC.

In dieser Arbeit wurden alle Proteine mit KdpD Domäne als KdpD Proteine zusammengefasst. Entsprechend ihrer Domänenarchitektur wurden KdpD Proteine in Kinasen, Nicht-Kinasen und dysfunktionale Kinasen eingeteilt, wobei die drei Gruppen nicht gleichmäßig innerhalb der Bakterienphyla verteilt sind. Es konnten verschiedene linienspezifische, evolutionäre Ereignisse, wie *kdpD* Genduplikation und häufiger horizontaler Gentransfer, nachgewiesen werden. Zudem wurde gezeigt, dass Domänenverschiebungen (*domain shuffling*) und Selektionsdruck auf Nukleotidsequenzen eine Umwandlung zwischen Kinasen und Nicht-Kinasen KdpD begünstigt. Durch eine Analyse des genomischen Kontextes von Nicht-Kinasen *kdpD* Genen in verschiedenen Bakterien wurden mehrere Arten von alternativen HK und RR entdeckt, die als alternative HK^{K+}/ RR^{K+} bezeichnet wurden und die möglicherweise die Induktion des *kdp* Operons als Antwort auf K^+ Limitierung regulieren. Einige der alternativen RR^{K+} wurden vorhergesagt, σ^{54}-abhängige Transkriptionsfaktoren zu sein. Um diese Vorhersage zu überprüfen, wurden K^+ sensitive Elemente des Kdp Systems von *Bacteroides fragilis* näher untersucht.

Um die Struktur der Kinasen oder Nicht-Kinasen KdpD Proteine mittels Kristallographie zu ermitteln wurden verschiedene Methoden angewendet, es konnte jedoch kein vielversprechendes Ergebnis erzielt werden. Aus diesem Grund wurde ein Protokoll entwickelt, um Kinasen KdpD für eine Cryo-EM in Nanodiscs einzuschließen.

CipA und CipB sind zwei niedermolekulare Proteine, die kristalline Proteineinschlüsse (protein crystalline inclusions, PCI) im Cytoplasma von *Photorhabdus luminescens* bilden. CipA und CipB wurden anfangs als Gerüst verwendet, um Proteine wie Nichtkinasen KdpD für die Kristallographie in PCIs zu organisieren. Die Mehrzahl der nachgewiesenen PCIs zeigte jedoch kein Beugungssignal.

Deshalb wurde das generelle biotechnologische Anwendungspotential von Cip Gerüsten in *E. coli* evaluiert. Auf der einen Seite konnten Proteine wie LacZ in PCIs eingeschlossen werden und *in vitro* isoliert werden, da PCIs wasserunlöslich und unempfindlich gegenüber hohen Temperaturen sind. Auf der anderen Seite konnte am Beispiel von Violacein gezeigt werden, dass es möglich ist, verschiedene Enzyme mit Hilfe von Cip Gerüste in funktionale Komplexe zu organisieren. Dies macht Cip Gerüste zu einem nützlichen Werkzeug für die Konstruktion metabolischer Prozesse (*metabolic engineering*).

8 Appendix

The appendix contains the following files and has been provided in the attached compact disc.

Figure A1: Archaeal *kdp* operon compositions. All *kdpD* genes (yellow colored arrows marked with “kdpD”) encode KdpD proteins with the domain architecture of KdpD-Usp-DU4118-GAF. HP, hypothetic protein, Usp-X, Usp-domain connecting with unpredicted domain.

Figure A2: KdpD-Usp protein tree with assigned KdpD domain architectures. This is supplementary to Figure 12 with additionally included KdpD domain architectures, protein IDs (in bracket) as well as species names. For branch color, blue: *kinase*, yellow: *dysfunctional kinase*, green: *non-kinase*. Proteins with domain architecture of KdpD-Usp-KdpD-Usp have two branches, because of two copies of “KdpD-Usp” (see the reason in Figure 11A) and the selected part for MSA is colored, while the other part is grey. Curves connecting KdpD proteins belong to the same species.

Figure A3: Genomic neighborhoods of some *non-kinase kdpD* genes. (A) Genomic neighborhoods of *non-kinase kdpD* genes encoding KdpD proteins with the domain architecture KdpD-Usp (yellow arrows marked “kdpD”) or KdpD-Usp-KdpD-Usp (yellow-green arrows marked “kdpD”). **(B)** Genomic neighborhoods of *non-kinase kdpD* genes encoding KdpD proteins with the domain architecture KdpD-Usp-DUF4118-GAF (yellow arrows marked “kdpD”) or KdpD-Usp-DUF4118 (yellow-green arrows marked “kdpD”). The genes encoding HK^{K+} and RR^{K+} are depicted as different colored arrows marked “hk” and “rr” or “sigma 54-related rr”, respectively. Domain architectures of corresponding HK^{K+} are also included (the “X” stands for an unpredicted domain). HP, hypothetical protein; OMP, outer membrane porin.

Data set:

Content of the appendix data set (including 9 sheets)	
Sheet Name	**Description**
Sheet 1	List of proteome IDs and taxon in the RFP
Sheet 2	Bacterial groups/phyla with KdpD protein(s)
Sheet 3	All KdpD proteins retrieved from the RFP
Sheet 4	All KdpA proteins retrieved from the RFP
Sheet 5	All TrkH proteins retrieved from the RFP
Sheet 6	All DUF4118 proteins retrieved from the RFP
Sheet 7	Taxonomy information of 216 KdpD proteins used for selection pressure analysis in Figure 14
Sheet 8	HK^{K+} and RR^{K+} of *non-kinase* KdpD
Sheet 9	σ^{54}-recognition motif detected in the *kdp* promoter in some *Bacteroidetes/Chlorobi* group and *Deltaproteobacteria*

Acknowledgement

At the first place, I would like to thank Prof. Dr. Kirsten Jung to give me the opportunity to work in her group. Under her supervision, I get to know much more about the mysteries of the simple, complicate and amazing microorganisms. We have differet languages, cultures and also different ways of thinking. I really appreciate her be accommodating. Her training me as PhD student is a great help to me and to my career.

My PhD study in Germany is sponsored by the China Scholarship Council. I appreciate this support very much.

Many thanks to the group members of AG Jungs, my colleagues: Prof. Heinrich Jung, Dr. Ralf Heermann, Dr. Frank Landgraf, Dr. Jürgen Lassak, Dr. Luitpold Fried, Dr. Stefan Behr, Dr. Matthias Reiger, Dr. Laure Plenera, Dr. Nicola Lorenz, Dr. Jae Yen Shin, Dr. Sophie Brameyer, Jannis Brehm, Simone Eckstein, Sophie Buchner, Ingrid Weitl, Korinna Burdack, Grazyna Wlodarska-Lauer, Ralph Krafczyk, Ana Gasperotti, Wolfram Volkwein, Miriam Pfab.

Many particular thanks to Hanah Shramke, Magdalena Motz, Bruno Pinheiro, Sabine Scheu, Angela Glaeser, Elisabeth Hoyer, Claudia Vilhena, Ivica Kristoficova.

I also like to thank the help of my collaborators Prof. Dr. Dirk Metzler, Dr. Noémie Becker and Dr. Sonja Grath (LMU) for their help on the evolutionary analysis of KdpD proteins and Mark Mimee of Dr. Timothy K. Lu's group (MIT) on the construction of *B. fragilis* reporter plasmids. Dr. Jörg Stetefeld of University of Manitoba for KdpD crystallization setpups. Thanks to Prof. Dr. Lars Redecke (Universität zu Lübeck) on X-ray test of the PCIs and Dr. Markus Hartl, Plant Science of LMU Munich for his kind help with mass spectrometry.

Many thanks to Prof. Dr. Michael Malamy (Tufts University) for kindly providing the plasmids pYT102 and pJST61 for genetic operation in *B. fragilis*.

感谢我的好友曾博，何海龙，武虓, 何秀丽这四年多来的陪伴。陪我度过每个快乐难忘的时光。

感谢我的家人和我的爱人对我无时无刻的支持与鼓励。

EDUCATION

Ph.D, Microbiology, Department of Biology I. LMU Munich. Martinsried, Germany. Expected, *May 2017.*

Dissertation: "Evolutionary and Structural Analysis of KdpD Proteins". *Advisor:* Prof. Dr. Kirsten Jung

M.A., Shandong University. Ji'nan, China. Metabolic Engineering and Synthetic Biology, State Key Laboratory of Microbial Technology. *July 2012.*

Thesis: "Metabolic Engineering of *Escherichia coli* and *Corynebacterium glutamicum* for Efficient Production of 5-Aminolevulinic Acid" (In Chinese). *Advisor:* Prof. Dr. Qingsheng Qi

B.S., Microbiology and Bioengineering, School of Life Science. Shandong Agricultural University. Tai'an, China. *July 2009.*

RESEARCH EXPERIENCE

2012.9-2017.3 Bioinformatics analysis the evolution history of KdpD proteins.

2015.12-2017.3 Characterization of the K^+- responding Kdp system of *Bacteroides fragilis*.

2012.9-2015.12 Structural analysis of KdpD proteins via protein crystallization and single particle cryo-EM.

2013.6-2014.12 Development of scaffold for organizing single or multiple proteins into *in vivo* protein crystalline inclusions for biotechnological applications.

2009.9-2012.7 Metabolic engineering of *Escherichia coli* and *Corynebacterium glutamicum* for high level production of 5-aminolevulinic acid or N-acetylneuraminic acid.

FELLOWSHIPS AND AWARDS

China Scholarship, 2012-2016

Guanghua scholarship, Shandong University, 2011

National Inspirational Scholarship, Shandong Agricultural University 2008

National Inspirational Scholarship, Shandong Agricultural University 2007
