# 1 Introduction

## 1.1 Actin and actin dynamics

Actin is one of the most abundant proteins in any eukaryotic cell as an essential component of the cytoskeleton and plays a central role in a number of motile activities such as cell migration, cell division and intracellular transport. It comprises a highly conserved family of proteins that fall into three broad classes:  $\alpha$ -,  $\beta$ -, and  $\gamma$ -isoforms. It is mainly located in the cytoplasm, but it is also found in the nucleus. Actin exists in two principal forms, globular, monomeric actin (G-actin), and filamentous polymeric actin (F-actin). The globular form is a 43 kDa monomer, while the filamentous form is a long-chained polar polymer. G-actin monomers have tight binding sites that enable head-to-tail interactions with two other actin monomers, so that they polymerize into thin, flexible F-actin, and F-actin also can depolymerize into single G-actin monomers reversibly. So, actin filaments are in a continuous state of assembly/disassembly (Fig. 1.1). This steady state is dependent on solvent conditions, particularly on the presence of certain actin binding proteins (ABPs) and/or actin ligands such as jasplakinolide[1] or latrunculin B[2].

**Figure 1.1 Actin dynamics-polymerization, depolymerization and branch formation**

The actin polymerization is divided into two steps. 1) *Nucleation*: G-actin monomers form an unstable dimer, and then become stabilized by addition of another G-actin monomer to form a tight trimer. 2) *Elongation*: Actin-trimers then polymerize to form filaments (F-actin) by further G-actin monomer addition. Actin binding protein Arp2/3 complex can nucleate filaments from the side of existing filaments to allow the filaments branch formation. In the meantime, F-actin can also depolymerize into G-actin by losing G-actin monomers from the side of filament.

Actin is a protein with the greatest variety of binding partners (such as ABPs, actin binding compounds). Due to its common expression and its many biological functions, actin has not been pushed as a clinically relevant drug target.

## 1.2 Actin binding proteins

### 1.2.1 Actin dynamics is regulated by actin binding proteins

Actin binds a vast number of proteins called actin binding proteins (ABPs). Actin participates in more protein-protein interactions than any other known protein, including the interaction of actin with itself and with ABPs[3]. In cells, the assembly and disassembly of actin filaments, and also their functions are modulated by various of ABPs [4-6] (Fig. 1.2). The activities of these proteins are in turn under the control of specific signaling pathways. Actin polymerizes from both ends of the filament, but the rate of polymerization at either end is different. The fast-growing end is called the barbed end (or plus-end) and the slow-growing end is called pointed end (or minus-end). Actin filaments elongate when ATP-actin monomers are combined at the barbed end. As the filament elongating, ATP bound in the central cleft of actin is hydrolyzed and phosphate is released. As a result, the ADP-actin filament is disassembled by losing monomers from the pointed end. The released ADP-actin monomers then undergo nucleotide exchange to generate ATP-actin monomers that can be used for a new round of polymerization. This typical phenomenon of steady filament dissociation/association is called actin treadmilling. For actin alone, the equilibrium is a dynamic exchange of monomers between the G-actin and the F-actin pool. This dynamics is modulated by various ABPs. These proteins include actin depolymerization proteins (like e.g. ADF/cofilin), capping/sequestering proteins (like e.g. thymosin  $\beta$ 4, Arp2/3 complex), severing proteins (like e.g. gelsolin), actin bundling protein ( $\alpha$ -actinin), ABPs that facilitate nucleotide exchanging (like e.g. profilin), and ABPs that promote branching (like e.g. Arp2/3 complex)[6].

**Figure 1.2 Actin binding proteins regulate actin dynamics**

The monomer-binding protein ADP/cofilin is involved in binding ADP-actin when it is released from pointed end. And profilin facilitates the nucleotide exchange of ADP-actin for ATP-actin and delivers the new ATP-actin monomers to barbed ends to facilitate new rounds of polymerization. As a monomer-sequestering protein, thymosin  $\beta 4$  can clamp ATP-actin to effectively block both barbed and pointed ends, preventing ATP-actin combined into the filaments. So that a large amount of ATP-monomer actins can be stored. When triggered by a certain signal, a rapid release of thymosin  $\beta 4$  binding will happen, and leads to a rapid filament extension. ADF/cofilin binds to ADP-F-actin and promotes dissociation of ADP-actin from the pointed end of filament, driving actin depolymerization. Arp2/3 complex can nucleate filament formation, elongate filaments, and establish branch points in actin networks. It also caps the pointed end, reduces the loss of monomers from pointed end and thereby leads to rapid filament extension. By contrast, the barbed end cappers such as gelsolin, it caps filament barbed end, blocks the addition of new ATP-monomers, controlling the overall length of the filament. As an actin bundling protein,  $\alpha$ -actinin can form an association of actin filaments[6].

### **1.2.2 Actin competes with ABPs and actin itself in a limited G-actin pool**

The actin cytoskeleton controls cells interaction with each other and their environment in a precise way. This is depending on the rearrangement of actin dynamics which is regulated by numerous different actin regulators, such as ABPs. A number of recent findings suggest that different actin assembly factors compete with one another for a finite G-actin pool. This competition limits actin and actin regulators activities and therefore a specific actin network and structures were formed as cell needs. Increasing or decreasing cellular G-actin influences the generation of F-actin network. For example, the actin monomer binding protein profilin is responsible for producing ATP-G-actin for assembly. Profilin also enhances formin-mediated and Ena/VASP-mediated actin filament elongation, leading linear filaments assembly[7, 8], which consequently inhibit Arp2/3 complex-mediated actin nucleation and branch formation. Thymosin  $\beta$ 4 clamps ATP-G-actin and control the amount of available ATP-G-actin for assembly. It was found that the formin and Arp2/3 complex compete with each other for G-actin and disruption of one frees more actin monomers for the other[9]. The competition between actin monomers, F-actin filaments and ABPs for binding to the available G-actin pool ensures cytoskeletal homeostasis and coordination between the different actin regulators to support dynamic cell behavior.

## **1.3 Actin cytoskeleton and disease**

### **1.3.1 The actin cytoskeleton is involved in fundamental functions in cell**

The actin cytoskeleton (actin and ABPs) plays a key role in intracellular transport, cell motility, control of cell shape and polarity, and distribution of macromolecules within cells[10] (Fig. 1.3). Reorganization of the actin cytoskeleton and expression of different actin isoforms are closely associated with cell differentiation processes[11]. This system is also involved in cell division[10]. The actin skeleton was shown to play an important role during programmed cell death, especially in apoptosis[12-14]. It has been shown that actin is also present in nuclei, where it plays a key role in nuclear matrix association, chromatin remodeling, RNA polymerase I, II, and III transcription, and mRNA processing[15].

**Figure 1.3 Biological functions of actin cytoskeleton in cells**

*Cell shape picture is retrieved from <http://www.scienceline.ucsb.edu/images/cell-shapes>.*

### 1.3.2 The actin cytoskeleton plays important role in the development of different diseases

The actin cytoskeleton, besides the above-mentioned fundamental functions in cell vital activity, also plays a key role in the development of different diseases. The role of the cytoskeleton and ABPs in disease is an emerging story. The actin microfilament system is involved in oncological processes (cell transformation, invasion[16], and metastasis[17]) and tissue fibrosis[18]. In particular, the metastatic disease, or the cancer cells movement, is a complex process requiring dramatic remodeling of the cell cytoskeleton[17]. Actin dynamics defects are a common feature contributing to neurodegeneration[19, 20]. The actin cytoskeleton is essential for invasion and infection by various viruses, bacteria, and other parasites[21]. All these processes largely depend on the polymerization and depolymerization of actin filaments, and the organization of actin into functional networks is of course regulated by ABPs. Factors regulating actin assembly become potential targets for preventing dissemination and invasion of tumor cells. Actin-dependent cellular processes, including tumor invasion, can be pharmacologically modulated by small-molecule inhibitors of actin assembly[22]. The inseparable element of the cancer progression, Epithelial-to-mesenchymal transition (EMT) and its reverse process MET

involve the acquisition of features such as invasiveness and migration potential. And the cell movement is due to changes in actin cytoskeleton reorganizations including polymerization and depolymerization of actin filaments[23]. The dynamics of this process can be regulated by actin-binding proteins such as cofilin-1 (CFL1) or special AT-rich sequence-binding protein 1 (SATB1)[24]. Profilin1 is required for normal mouse brain development, which relies on profilin1 regulation of actin[25]. Thus, a better understanding of the molecular mechanisms of ABPs controlling actin cytoskeleton provides cues for the treatment of these diseases. The feasibility of modifying the behavior of ABPs as a therapeutic approach for disease is a considerable need.

## 1.4 Actin binding natural compounds

### 1.4.1 Actin binding natural compounds: promising actin targeting compounds in a therapeutic setting

Though actin binding natural compounds are known for more than 45 years[26], none of them has made it into clinics yet for reasons of lacking functional selectivity. The large number of actin binding compounds we know today is mainly of natural origin (fungi, bacteria, marine organisms) and can be roughly divided into two groups: 1) actin filament stabilizers (phalloidin 1975[27], jasplakinolide 1994[28]), and 2) actin filament assembly inhibitors or destabilizers (kabiramide C 1993[29], latrunculin 1983[30]). The discovery of actin binding compounds has immensely fueled our knowledge about the biology of actin, and these natural compounds mentioned above have already become standard tools in cell biology.

Although, during the past years, we have learned that the complexity of actin biology goes far beyond the regulation of overall polymerization and depolymerization[31]: actin does not merely form polymers with other actin molecules and subsequently depolymerize again. Rather, ABPs continuously compete with each other for binding sites on actin (e.g. thymosin  $\beta$ 4 with profilin[32], or MRTF with G-actin[33]) and with actin itself[31]. This complex network allows for subtle control of the “actin-interactome” and related cell functions. Small actin-binding molecular compounds have been found to, in turn, compete with specific actin-binding proteins. For example, kabiramide C has been shown to compete with actin capping proteins like gelsolin in a kind of “molecular mimicry”[34]. This aspect of the interaction between small molecular inhibitors and actin has been largely neglected during the characterization discovery. The effect of actin-binding compounds on the cellular level has

yet to be discovered. And the use of actin targeting natural compounds in a therapeutic setting has to be considered in spite of their availability. It would open a new field of biological tools or even therapeutic options by developing novel and much more specific actin targeting compounds.

#### 1.4.2 Miuraenamide A - a new actin stabilizer

Myxobacteria produce a variety of natural compounds that interfere with the dynamics of cytoskeleton structures of eukaryotic cells, such as chondramides[35], disorazoles[36], and rhizopodins[37].

A novel myxobacterial compound miuraenamide A, is presumed to be an actin filament stabilizing agent[38]. Miuraenamide A is a cyclodepsipeptide antibiotic that was isolated from *Paraliomixa miuraensis*, a slightly halophilic myxobacterium discovered in Japan in 2006[39]. The absolute stereostructure of miuraenamide A was soon determined in 2008[40]. Miuraenamide A shows antimicrobial activity, inhibits NADH oxidase, and stabilizes actin filaments[38-40]. Miuraenamide A also shows high cytotoxicity to a range of tumor cell lines[41]. The  $\beta$ -methoxyacrylate moiety of miuraenamide A is known to be important for its antimicrobial activity[40], but its influence on actin binding is still unclear. Comparable biological effects of Miuraenamide A were observed with other cyclodepsipeptides, such as chondramide[42] and jasplakinolide[35], which is not surprising on the basis of their closely related structures (Fig. 1.4). Owing to its interesting biological activities, the synthesis of miuraenamides was soon obtained by a peptide modification approach in 2015[41]. Further investigations on the characterization of miuraenamide A binding to actin is promising.

**Figure 1.4 Structures of cyclodepsipeptides**

(adapted from Karmann L et al. 2015[41])

### 1.4.3 Chivosazole A - a new actin destabilizer

Chivosazoles are 31-membered macrolides with one oxazol ring that were originally discovered in different strains of the myxobacterium *Sorangium cellulosum*, the main representative of which is chivosazole A[43] (Fig. 1.5). The chivosazoles are glycosides of 6-deoxyglucose derivatives. Additionally, the simple aglycon of chivosazole A, was isolated and named chivosazole F. The chivosazole family shows a potent antiproliferative activity against different mammalian cell lines including human cancer cell lines. Chivosazoles show antimicrobial activity against yeasts and filamentous fungi[43]. Chivosazoles are cytotoxic against mouse fibroblasts (L-929), inducing a clearly morphological changes different from those induced by rhizopodin. Chivosazoles destabilize pyrene F-actin, while rhizopodin and cytochalasin D do not[44]. This reveals that chivosazoles inhibit actin polymerization through specific binding to G-actin, thereby leading to disruption of cytoskeletal dynamics. The absolute and relative configuration of chivosazole A has been assigned in 2007 [45], prompting the chemical synthesis of this very potent natural product. The synthesis of the chivosazoles was shown to be feasible in 2017[46]. As a result, the exact binding site and action mode of chivosazole A are likely to be distinct, thus making it a novel, selective tool for the investigation of actin cytoskeleton, as well as a promising antimicrofilament lead candidate for drug discovery.

**Figure 1.5 Structure of chivosazole A and F**

(adapted from Diestel R et al. 2009[44])

## 1.5 Aim of the study

We wanted to perform an in-depth characterization of these two novel myxobacterial compounds miuraenamide A (in comparison to the classical actin stabilizer jasplakinolide) and chivosazole A (in comparison to a structurally unrelated actin filament inhibitor latrunculin B[2])

- in vivo on cellular function and on transcriptional regulation
- in vitro on actin dynamics and protein-protein-interactions of actin
- through co-crystallization and structure determination to reveal their actin binding mode

in order to find out new and more specific actin targeting compounds and develop them into a new field of biological tools or even therapeutic options instead of just “stabilizers” or “destabilizers”.

## **2 Materials and Methods**

## 2.1 Materials

### 2.1.1 Compounds

Miuraenamamide A (MiuA) was kindly provided by Prof. Dr. Uli Kazmaier (Institute for Organic Chemistry, Saarland University, Saarbrücken, Germany). Jasplakinolide (Jaspla) was purchased from Santa Cruz (Heidelberg, Germany). Chivosazole A (ChivoA), Chivosazole F (ChivoF) and Rhizopodin were kindly provided by Prof. Dr. Rolf Müller (Helmholtz Center for Infection Research, Saarland University, Saarbrücken, Germany), isolated from myxobacterial strains. Latrunculin B was purchased from Biomol GmbH (Hamburg, Germany).

All compounds were dissolved in dimethyl sulfoxide (DMSO) and stored at -20 °C. For cell experiments, they were further diluted in endothelial cell growth medium (ECGM) with a maximum end concentration of DMSO of 0.1% (v/v). For TIRF and actin-binding experiments, they were further diluted in DMSO.

### 2.1.2 Chemicals and reagents

The following table contains a list of all chemicals, reagents and kits used in this study. Buffers and solutions are listed separately.

**Table 2.1: Chemicals and reagents**

Reagent	Producer
Adenosine 5'-triphosphate (ATP)	Sigma-Aldrich, Taufkirchen, Germany
Actin (rabbit skeletal muscle)	Hypermol, Bielefeld, Germany
Actin-Toolkit G-actin binding	Hypermol, Bielefeld, Germany
Actin-Toolkit F-actin binding	Hypermol, Bielefeld, Germany
$\alpha$ -actinin (turkey gizzard smooth muscle)	Hypermol, Bielefeld, Germany
Arp2/3 complex (porcine brain)	Hypermol, Bielefeld, Germany
ATP-Sucrose cushion	Hypermol, Bielefeld, Germany
Atto488-Actin (rabbit skeletal muscle)	Hypermol, Bielefeld, Germany
Amphotericin B	PAN-Biotech, Aidenbach, Germany
Bovine Serum Albumin (BSA)	Sigma-Aldrich, Taufkirchen, Germany
CaCl <sub>2</sub>	Sigma-Aldrich, Taufkirchen, Germany
Catalase	Sigma-Aldrich, Taufkirchen, Germany

Cofilin (non muscle cofilin)	Hypermol, Bielefeld, Germany
Collagen G	Biochrom AG, Berlin, Germany
Coomassie Brilliant Blue R-250 staining solution	Bio-Rad, Munich, Germany
Coomassie Brilliant Blue R-250 destaining solution	Bio-Rad, Munich, Germany
Crystal violet	Carl Roth, Karlsruhe, Germany
D-glucose	Sigma-Aldrich, Taufkirchen, Germany
Dimethyl sulfoxide (DMSO)	Sigma-Aldrich, Taufkirchen, Germany
Dithiothreitol (DTT)	SERVA Electrophoresis, Heidelberg, Germany
Dulbecco's Modified Eagle Medium (DMEM)	PAA Laboratories, Pasching, Austria
Endothelial cell growth medium (ECGM)	Pelobiotec, Martinsried, Germany
Ethanol	Carl Roth, Karlsruhe, Germany
Ethylendiaminetetraacetic acid (EDTA)	Sigma-Aldrich, Taufkirchen, Germany
Ethylene glycol-bis(2-aminoethylether)-N,N,N',N'-tetraacetic acid (EGTA)	Sigma-Aldrich, Taufkirchen, Germany
F-Actin BufferKit REF 5300-01	Hypermol, Bielefeld, Germany
Fetal calf serum (FCS)	Biochrom AG, Berlin
FluorSave® reagent mounting medium	Merck, Darmstadt, Germany
Glucose oxidase from Aspergillus Niger	Sigma-Aldrich, Taufkirchen, Germany
GST-VCA (recombinant, human)	Hypermol, Bielefeld, Germany
Hoechst 33342	Sigma-Aldrich, Taufkirchen, Germany
Imidazole	Sigma-Aldrich, Taufkirchen, Germany
KH <sub>2</sub> PO <sub>4</sub>	Carl Roth, Karlsruhe, Germany
KCl	Carl Roth, Karlsruhe, Germany
Corning®, Matrigel®, REF 356231	Corning, NY, USA
Methanol	Carl Roth, Karlsruhe, Germany
Methylcellulose	Sigma-Aldrich, Taufkirchen, Germany
MgCl <sub>2</sub>	AppliChem, Darmstadt, Germany
MgSO <sub>4</sub> • 7H <sub>2</sub> O	Carl Roth, Karlsruhe, Germany
Na <sub>3</sub> C <sub>6</sub> H <sub>5</sub> O <sub>7</sub>	Carl Roth, Karlsruhe, Germany
NaCl	Carl Roth, Karlsruhe, Germany
Na <sub>2</sub> HPO <sub>4</sub>	Merck, Darmstadt, Germany
Formaldehyde, 16%, methanol free, Ultra Pure	Polysciences Inc., Warrington, PA, USA
Penicillin/Streptomycin	PAN Biotech, Aidenbach, Germany
Prestained protein ladder PageRuler™	Bio-Rad, Munich, Germany

Pyrene Actin 10% (rabbit skeletal muscle)	Hypermol, Bielefeld, Germany
Rhodamin phalloidin	Sigma-Aldrich, Taufkirchen, Germany
Sodium dodecyl sulfate (SDS)	Carl Roth, Karlsruhe, Germany
Streptomycin	PAN Biotech, Aidenbach, Germany
Tris-Base	Sigma-Aldrich, Taufkirchen, Germany
Tris-HCl	Sigma-Aldrich, Taufkirchen, Germany
Triton X-100	Merck, Darmstadt, Germany
Trypsin	PAN Biotech, Aidenbach, Germany
$\beta$ -Mercaptoethanol	Sigma-Aldrich, Taufkirchen, Germany

**Table 2.2: Consumables**

Product	Producer
Cell culture flasks 75cm <sup>2</sup>	TPP, Trasadingen, Switzerland
Corning® 96 Well Black Polystyrene Microplate REF3686	Corning Incorporated, NY, USA
Cover slip (8 × 8 mm)	H.Saur Laborbedarf, Reutlingen, Germany
Cover slip (22 × 22 mm)	Th.Geyer GmbH, Renningen, Germany
Disposable pipettes: 5 ml, 10 ml, 25 ml	Greiner Bio, Frickenhausen, Germany
Falcon tubes: 15 ml, 50 ml	VWR, Bruchsal, Germany
Glass slide (Microscope Slides 76 × 26 mm)	Thermo scientific, Braunschweig, Germany
Microcentrifuge Tubes: 1.5ml	Beckman Coulter, Krefeld, Germany
Microtiter plates: 96 well	Greiner Bio, Frickenhausen, Germany
Microtubes: 1.5 ml, black	Carl Roth, Karlsruhe, Germany
Microtubes: 1.5 ml, brown	Sarstedt AG & Co.KG, Nuembrecht, Germany
Parafilm	American National Can, Chicago, USA
Pipette tips: 10 $\mu$ l, 100 $\mu$ l, 1000 $\mu$ l	Sarstedt, Nümbrecht, Germany
Safe-Lock Tubes: 0.5 ml, 1.5 ml, 2.0 ml	Eppendorf, Hamburg, Germany
$\mu$ -Slide 8 Well	Ibidi GmbH, Munich, Germany
$\mu$ -Slide Angiogenesis	Ibidi GmbH, Munich, Germany

μ-Slide Chemotaxis

Ibidi GmbH, Munich, Germany

### 2.1.3 Technical equipment

**Table 2.3 Technical equipment**

Technical equipment	Producer
Axiovert 25 / m200	Zeiss, Jena, Germany
ChemiDoc™ Touch Imaging System	Bio-Rad Laboratories, Munich, Germany
Digital block heater HX-1	PEQLAB Biotechnologie, Erlangen, Germany
Heracell CO <sub>2</sub> Incubator 150i	Thermo Fisher Scientific, MA, USA
Heraeus Megafuge 1.0 RS centrifuge	Kendro Laboratory Products, Hanau, Germany
Ibidi stage top incubation system	Ibidi GmbH, Munich, Germany
IKA Vibrax VXR Basic shaker	IKA-Werke, Staufen Germany
Infinite® 200 PRO microplate reader	Tecan, Männedorf, Switzerland
LSM 510 Meta confocal microscope	Zeiss, Jena, Germany
Mikro 220 / 220 R microliter centrifuge	Hettich, Tuttlingen, Germany
Mini-PROTEAN® 3	Bio-Rad, Dreieich, Germany
Nanodrop® ND-1000	Peqlab, Wilmington, USA
Optima TLX Ultracentrifuge	Beckman Coulter, Fullerton, CA, USA
Power Pac 300 blotting device	Bio-Rad, Dreieich, Germany
SpectraFluor Plus™ microplate reader	Tecan, Männedorf, Switzerland
Thermo Haake W19 open-bath circulator	Thermo Fisher Scientific, MA, USA
Total internal reflection fluorescence microscope (TIRFM)	Leica Microsystems, Wetzlar, Germany
Vi-Cell™ XR	Beckman Coulter, Fullerton, CA, USA
Nikon inverted microscope Eclipse Ti	Nikon corporation, Tokyo, Japan

## 2.2 Methods

### 2.2.1 Cell culture

The human umbilical vein endothelial cells (HUVECs) are primary cells purchased from Promocell (Heidelberg, Germany). The company guarantees an ongoing quality control (e.g. expression of endothelial markers). Further authentication is not necessary, since these are primary cells. The cells were cultured with endothelial cell growth medium (Promocell), supplemented with 10% FCS under constant humidity at 37 °C and with 5% CO<sub>2</sub>. Upon confluency, cells were splitted in a ratio 1:3 in a 75 cm<sup>2</sup> cell culture flasks. Cells were used for functional assays at passage 6.

**Table 2.4 Cell culture solutions and reagents**

<b>Endothelial cell growth medium (ECGM)</b>		<b>Freezing medium</b>	
Endothelial cell growth medium	500 ml	DMEM	70%
(with supplement kit)		FCS	20%
FCS (heated)	50 ml	DMSO	10%
Amphotericin*	5 ml		
Pen / Strep*	5 ml		
<b>Stopping medium</b>		<b>Starvation medium</b>	
DMEM	500 ml	DMEM	500 ml

### 2.2.2 Passaging

For passaging, cell medium was removed, cells were washed twice with PBS and detached with 1.5 ml Trypsin/EDTA (37 °C, 3 min). After incubation, tryptic digestion was stopped by adding 15 ml stopping medium. Cells were centrifuged (1000 rpm, 5 min, 20 °C), resuspended in ECGM. Cell concentration and vitality were determined by using Vi-Cell™ XR. Then cells were either transferred into a new cell culture flask (75 cm<sup>2</sup>, pre-coated with Collagen G) or seeded for experiments.

### 2.2.3 Freezing and thawing

For long time storage, a 75 cm<sup>2</sup> flask of confluent HUVECs were detached by Trypsin/EDTA and collected by centrifugation (1000 rpm, 5 min, 20 °C). Cells were then resuspended in 3 ml ice-cold freezing medium. 1.5 ml aliquots were frozen in cryovials and stored at -80 °C for 24 h before being moved to liquid nitrogen (-196 °C) for longtime storage. In order to thaw cells, cells in cryovials were immediately dissolved in pre-warmed stopping medium.

DMSO was removed by centrifugation, cells were resuspended in 15 ml pre-warmed ECGM and transferred into a 75 cm<sup>2</sup> flask (pre-coated with Collagen G).

## 2.3 Proliferation Assay

HUVECs ( $1.5 \times 10^3$  cells/well) were seeded in 96-well plates (pre-coated with Collagen G). After 24 h incubation, cells in a reference plate were stained with crystal violet and served as initial control. The cells in a treatment plate were either left untreated or treated with indicated concentrations of compounds respectively for 72 h. After treatment, the medium was removed and cells were stained with crystal violet staining solution for 10 min, then washed with water and dried overnight. Cell-bound crystal violet was dissolved with sodium citrate solution (5 min, shaking) and the absorbance which correlates with cell number was measured at 550 nm using a microplate reader (SpectraFluor Plus™). For statistical analysis, cells treated with vehicle control were set to be 100%.

**Table 2.5 Crystal violet and sodium citrate buffer.**

Crystal violet staining solution		Sodium citrate solution	
Crystal violet	0.5%	Na <sub>3</sub> C <sub>6</sub> H <sub>5</sub> O <sub>7</sub>	0.05 M
Methanol	20%	Ethanol	50%
H <sub>2</sub> O		H <sub>2</sub> O	

## 2.4 Fluorescence imaging

HUVECs ( $25 \times 10^3$  cells/well) were seeded in an 8 well ibidi  $\mu$ -slide (pre-coated with Collagen G), pretreated with indicated concentrations of compounds. After 1 h treatment, cells were rinsed with PBS + Ca<sup>2+</sup>/Mg<sup>2+</sup> and fixed with 4% (v/v) formaldehyde for 10 min. After 5 min washing with PBS, samples were permeabilized for 2 min with 0.2% Triton X-100 in PBS. After 3  $\times$  5 min washing with PBS, cells were incubated with rhodamine phalloidin (1:400) and Hoechst 33342 (1  $\mu$ g/ml) for 1 h at room temperature, then washed again 3  $\times$  5 min with PBS and sealed with one drop of FluorSave reagent mounting medium and covered by cover slips (8  $\times$  8 mm). Images were taken using a Zeiss LSM 510 META confocal microscope.

## 2.5 Cell migration assay

### 2.5.1 Scratch assay

To examine the migratory ability of HUVEC cells under the influence of various compounds, scratch assay was performed first. For the scratch assay, HUVECs were seeded into 96-well plates (Collagen G pre-coated), incubated overnight. Then confluent HUVECs were scratched with a custom-made tool and either left untreated or treated with the indicated concentrations of compounds. Cells were allowed to migrate for 16-24 h, then washed with 100  $\mu$ l/well PBS (including  $Mg^{2+}$ ,  $Ca^{2+}$ ), stained with 100  $\mu$ l/well Crystal Violet solution for 10 min, washed with water, and dried. Images were taken using a standard inverted microscope. Image analysis was performed with ImageJ. Migration was quantified as the percentage of cell covered area compared with the total image area.

### 2.5.2 2D and 3D Chemotaxis

Chemotaxis experiments were conducted according to the manufacturer's instructions. For the 2D-chemotaxis assay, HUVECs ( $50 \times 10^3$ /well) were seeded in a  $\mu$ -Slide Chemotaxis, either left untreated or treated with indicated concentrations of compounds and incubated to be slightly adherent to the surface of the observation area. After 2 h, ECGM with a gradient of FCS between 0 and 10% (v/v) was applied into the slide (Fig. 2.1). For 3D-chemotaxis assay, HUVECs ( $50 \times 10^3$ /well) were seeded in matrigel in the observation area of a  $\mu$ -Slide Chemotaxis, either left untreated or treated as indicated and incubated. After 0.5 h, ECGM with a gradient FCS between 0 and 10% (v/v) was applied (Fig. 2.2).

Time lapse image sequences of HUVEC cell migration were taken every 10 min for 21 h using a Nikon inverted microscope Eclipse Ti, equipped with ibidi stage top incubation system (37 °C, 5% CO<sub>2</sub>, 80% humidity). Single cell tracking was performed using ImageJ software plugin "Manual tracking" (Version 2.0 with ImageJ Plugin). Images were analyzed using the Chemotaxis and Migration Tool (ibidi, Martinsried, Germany). Cell mean velocity, directness and X-forward migration index (X-FMI) were calculated as parameters.

**Figure 2.1 2D Chemotaxis experiments without gel**

(adapted from Application note 17: Chemotaxis 2D and 3D, ibidi GmbH, Munich, Germany)

**Figure 2.2 3D Chemotaxis experiments in matrigel**

(adapted from Application note 17: Chemotaxis 2D and 3D, ibidi GmbH, Munich, Germany)

## 2.6 Tube formation assay

To investigate the effect of our compounds on HUVECs tube formation ability, tube formation assay was performed. For tube formation assay, HUVECs ( $10 \times 10^3$  cells/well) were seeded in matrigel in a  $\mu$ -Slide Angiogenesis, either left untreated or treated with various compounds as indicated and incubated for tube formation. After 16 h, images of the cells were taken using a Nikon standard inverted microscope Eclipse Ti and analyzed by Wimasys GmbH (Munich, Germany). As parameters of tube formation, total branching points, total loops, total tubes and mean tube length were used.

## 2.7 Pyrene assay

To investigate the effect of our compounds on actin polymerization, pyrene assay was performed. This assay is based on the enhanced fluorescence of pyrene conjugated actin that occurs during polymerization. The enhanced fluorescence that occurs when pyrene G-actin (monomer) forms pyrene F-actin can be measured in a fluorimeter to follow polymerization over time.

Pyrene assay was performed using Pyrene Actin (10%) and F-Actin BufferKit according to the manufacturer's instructions. Pyrene Actin (10%) was diluted with H<sub>2</sub>O to a 1 mg/ml (24 µM) stock solution. Before use, spontaneously formed actin aggregates were removed by ultracentrifugation for 1 h at 40,000 rpm and 4 °C. 50 µl samples for the pyrene assay consisted of: 30 µl H<sub>2</sub>O, 10 µl 10 mM MgCl<sub>2</sub> or 250 mM KCl, 5 µl F-actin Buffer (100 mM Imidazole-Cl pH 7.4, 10 mM ATP) as well as 5 µl DMSO (containing indicated concentrations of compounds/proteins) were added into a 96 well black polystyrene microplate immediately before the rapid addition of 10 µl pyrene actin to start polymerization. Pyrene fluorescence was monitored every 20 s over 1 h in a 96-well fluorescence plate reader (Infinite® 200 PRO) at 360 nm excitation and 400 nm emission wavelength.

## 2.8 TIRF assays

### 2.8.1 Flow cell preparation

Flow cells containing 15 - 20 µl of fluid were prepared as a sandwich of a cover slip (22 × 22 mm), 2 parafilm strips forming an approximately 5 mm wide channel, and a glass microscope slide (76 × 26 mm). Both, the coverslip and the glass slide were cleaned by ethanol and dried. The chamber was heated briefly and cooled to melt the parafilm strips to the glass slide surface and the cover slip. For TIRF microscope, chambers were used with the cover slip down, facing the objective lens, and slide up (Fig. 2.3). Solutions were loaded directly into the chamber via capillary action.

**Figure 2.3 Scheme of flow cell and the visualization of single actin filaments using TIRF microscopy**

*Growing actin filaments attach to  $\alpha$ -actinin on the coverslip surface. (adapted from Breitsprecher D et al. 2009[47])*

### 2.8.2 Protein and TIRF buffer preparation

Atto488-Actin and Actin from rabbit skeletal muscle were purchased from Hypermol (Bielefeld, Germany). Both Atto488-Actin and Actin were reconstituted with H<sub>2</sub>O to obtain a 1 mg/ml stock. Labeled actin was prepared by mixing Atto488-Actin and Actin 1:1 v/v. Protein concentration was determined by measuring OD at 290 nm ( $\epsilon_{290} = 26,600 \text{ M}^{-1}\text{cm}^{-1}$ ) using Nanodrop® ND-1000[48].

$\alpha$ -actinin from turkey gizzard smooth muscle was purchased from Hypermol (Bielefeld, Germany) and was prepared by adding 1 ml H<sub>2</sub>O to the tube with  $\alpha$ -actinin to obtain a working stock of 1 mg/ml.

**Table 2.7 Buffers for TIRF assays**

<b>G-buffer (pH 7.8)</b>		<b>10 × KMEI buffer (pH 7.1)</b>	
Tris-HCl (pH 8.0)	2 mM	KCl	500 mM
CaCl <sub>2</sub>	0.2 mM	MgCl <sub>2</sub>	20 mM
DTT	0.5 mM	EGTA	20 mM
ATP	0.2 mM	Imidazole	300 mM
H <sub>2</sub> O		H <sub>2</sub> O	
Added before use:			
MgATP	0.2 mM		
<b>2 × TIRF buffer (pH 7.4)</b>		<b>F-buffer</b>	
10 × KMEI buffer	20% (v/v)	10 × KMEI buffer	10% (v/v)
D-glucose	30 mM	G-buffer	90% (v/v)
Catalase	40 µg/ml		
Glucose oxidase	400 µg/ml		
Methylcellulose	1%(w/v)	<b>10 × Mg exchange buffer</b>	
β-mercaptoethanol	2%(v/v)	MgCl <sub>2</sub>	400 µM
G-buffer		EGTA	2 mM

**2.8.3 Nucleation and polymerization assay**

Freshly prepared flow cells were first incubated with 25 µl 1% (w/v) BSA for 10 min, then 25 µl α-actinin (1 mg/ml) was applied into the flow cell and incubated for 5 min. In the meantime, labeled actin (10 µM) was incubated 1:1 v/v with 1/10 volume of 10 × Mg exchange buffer and 1:8 v/v with G-buffer for 5 min on ice to convert Ca-ATP-actin to Mg-ATP-actin. Flow cell was then washed with 30 µl of G-buffer. 2 × Mg-ATP-actin (1 µM) was mixed 1:1 v/v with 2 × TIRF buffer containing different compounds as indicated, and the polymerization started. 30 µl polymerizing actin were immediately loaded into the flow cell chamber and placed on the TIRF microscope to start image acquisition. For nucleation

assay, the amount of actin nuclei present in each frame was analyzed using programs custom-written in MATLAB (The MathWorks, Natick, MA) R2017a. For polymerization assay, fluorescence image sequences of actin polymerization were taken every 1 s for 5 min. Elongation rates were calculated by Image J software (version 1.49).

#### **2.8.4 Depolymerization assay**

Labeled F-actin was obtained by incubating labeled actin (10  $\mu$ M) 1:1 v/v with 1/10 volume of 10  $\times$  KMEI buffer and 1:8 with G-buffer for 1 h at room temperature. 20  $\mu$ l 1:4 v/v diluted F-actin filaments (with F-buffer) were loaded into a flow cell previously blocked with 1% BSA and coated with 1 mg/ml  $\alpha$ -actinin. Then 50  $\mu$ l 2  $\times$  TIRF buffer with indicated compounds were applied gently into the flow chamber and immediately placed on the TIRF microscope to start image acquisition. The real time actin depolymerization process in a single frame was captured as image sequence every 15 s for 90 min. The average length of actin filaments was quantified as depolymerization parameter by using custom-written programs in MATLAB.

#### **2.8.5 Phalloidin competition assay**

For the phalloidin competition assay, labeled F-actin (prepared as described) was loaded into a freshly coated flow cell. TIRF buffer with 16.5 nM rhodamine-phalloidin, as well as different concentrations of Miuraenamides A as indicated were applied into the flow chamber and immediately placed on the TIRF microscope to start image acquisition. Different frames of fluorescent actin filaments were taken. Phalloidin  $\Delta$ intensity and IC 50 of Miuraenamide A were calculated by using ImageJ software (version 1.49).

#### **2.8.6 Branch formation assay**

To observe actin branch formation, labeled actin was incubated with Mg exchange buffer to obtain Mg-ATP-actin as described. 2  $\times$  Mg-ATP-actin (1  $\mu$ M) was mixed 1:1 v/v with 2  $\times$  TIRF buffer containing Arp2/3 complex, GST-VCA and various compounds as indicated, then immediately loaded into a coated flow chamber and placed on the TIRF microscope to start image acquisition. A single frame of actin fluorescence was recorded every 2 s for 10 min.

## 2.9 Actin binding assay

### 2.9.1 G-actin binding assay

The G-actin binding assay was performed using 'Actin-Toolkit G-Actin Binding' according to manufacturer's instructions. In this kit G-actin is coupled to Sepharose™ as G-actin beads. Binding of ABPs to G-actin is highly specific, and thus, the ABPs bound to G-actin will be co-precipitated under low centrifugal forces. G-actin beads (1/4 volume of 1 tube) were pre-treated with our compounds as indicated for 30 min at room temperature under agitation, then the ABPs (gelsolin, profilin, cofilin or Arp2/3 with GST-VCA) were added respectively, incubated for 1 h at room temperature. After incubation, sample was spun (6,000 × g, 4°C, 4 min) and 40 µl supernatant were mixed with 10 µl 5 × SDS-sample buffer. Then the G-actin beads were washed, resuspended in 25 µl of 1 × SDS-sample buffer and boiled at 95°C for 5 min. Both the supernatant and the G-actin beads (15 µl of each) were separately loaded onto an SDS-PAGE gel for analysis. After electrophoresis, the gel was stained in Coomassie Brilliant Blue R-250 staining solution for 60 min, rinsed in deionized water and then fixed in Coomassie Brilliant Blue R-250 destaining solution for 60 min at room temperature or overnight at 4°C. The stained gel was imaged using a ChemiDoc Imaging System. The amounts of each protein were quantified by using Image Lab 6.0 Software.

### 2.9.2 F-actin binding assay

F-actin binding assay was performed using 'Actin-Toolkit F-Actin Binding' according to manufacturer's instructions. F-actin is prepared by polymerizing G-actin with PolyMix (1 M KCl, 0.02 M MgCl<sub>2</sub>, 0.01 M ATP, 0.1 M imidazole pH 7.4) for 30 min at room temperature. 250 µl F-actin sample mix were prepared by incubating F-actin with each of our compounds as indicated for 30 min in PolyMix at room temperature, then the respective F-actin binding protein (cofilin, gelsolin, or Arp2/3 complex with GST-VCA) was added, incubated for 1 h at room temperature (the molar ratio of F-actin and ABP was 1:1). During sample incubation the sucrose cushions was prepared by adding 50 µl sucrose solution to the centrifuge tube. After incubation, 40 µl of the sample mix were prepared (mixed with 10 µl of 5 × SDS-sample buffer) for a total SDS-PAGE sample. 200 µl of the rest sample was added into the centrifuge tube overlaying the sucrose cushion. Pelleting of F-actin binding proteins was achieved by spinning the rest of the sample at 100,000 × g, at 4 °C for 1 h. After centrifugation, 40 µl of the supernatant were prepared (mixed with 10 µl of 5 × SDS-sample buffer) as a supernatant sample for SDS-PAGE. The pellets were dissolved in 200 µl 1 ×

SDS-sample buffer, boiled at 95°C for 5 min and then 15 µl of each SDS-sample (total, supernatant and pellet) was loaded into an SDS-PAGE gel separately to observe F-actin binding after electrophoresis. The gel was then stained by coomassie blue as described in G-actin binding assay. After staining the gel was captured by using a ChemiDoc Imaging System. The amounts of each protein were quantified by using Image Lab 6.0 Software.

### 2.9.3 Crosslink assay

Cross-linking of thymosin  $\beta$ 4 to G-actin was performed by using EDC as a cross-linker. Binding of thymosin  $\beta$ 4 to G-actin could be detected after crosslinking. The molecular weight of cross-link product was approximately 47.5 kDa.

G-actin (27 µM) was dissolved in crosslink G-buffer (3 mM triethanolamine-HCl, 0.2 mM  $\text{CaCl}_2$ , 0.2 mM ATP,  $\text{NaN}_3$ , pH 7.5) and incubated with either ChivoA or LatB as indicated at 4 °C for 30 min. Then thymosin  $\beta$ 4 was applied and incubated at 4 °C for 45 min at a weight ratio of 9:1, corresponding to 0.94 molecules of thymosin  $\beta$ 4 per actin monomer. Aliquots of 10 µl were then mixed with 12.2 µl of 5.4 mM EDC (1-ethyl-3-(3-dimethylaminopropyl)- carbodiimide) in 0.1 M MES (2-(N-morpholino)-ethanesulfonic acid), pH 6.5, and incubated for 2 h at 25 °C. Equal aliquots were taken up into SDS sample buffer and analyzed by SDS-PAGE on a 10% gel to detect cross-link product. After electrophoresis gel was then stained by coomassie blue as described in G-actin binding assay. After staining the gel was captured by using a ChemiDoc Imaging System. The amounts of each protein were quantified by using Image Lab 6.0 Software. Cross-link product was quantified as a normalized gray intensity of cross-link product band compared with actin.

### 2.9.4 SDS-PAGE

The SDS-PAGE gels were prepared in a discontinuous manner, with a stacking gel on top of the separation gel. The concentrations of acrylamide in the separation gels were adjusted to optimize the separation of proteins according to their molecular weights.

The Mini-PROTEAN 3 electrophoresis module was used. Prior to sample loading, the apparatus was assembled according to manufacturer's protocol and the chamber was filled with electrophoresis buffer. Equal amount of samples were loaded on to the stacking gel. An equal volume of 1 x SDS-sample buffer containing 2 µl of prestained protein ladder PageRuler™ was loaded on each gel to estimate the molecular weights of the separated proteins. Electrophoresis was carried out at 100 V for 21 min for protein stacking, then at 200 V for 35-45 min for protein separation.

**Table 2.8 Buffers for SDS-PAGE analysis**

<b>5x SDS-sample buffer</b>		<b>1x SDS-sample buffer</b>

## **2.10 Assessment of the transcriptome**

HUVECs at 80 % confluency were treated with equipotent concentrations of 60 nM MiuA, 120 nM Jaspla, 20 nM ChivoA or 250 nM LatB respectively for 4 h. The concentrations were chosen in order to stay below levels causing visible alterations of cell morphology and overall actin structure. Samples for transcriptome analysis were prepared by F. Gegenfurtner. Transcriptome analysis was performed by Prof. Dr. Wolfgang Enard (Department Biology II, Ludwig-Maximilians University Munich, Germany).

## **2.11 Quantification and statistical analysis**

Quantitative data are expressed as mean  $\pm$  SEM. Statistical analysis was performed using the software GraphPad Prism Version 7.02 (GraphPad Software, Inc., La Jolla, CA, USA). Statistical differences were evaluated by using Kruskal - Wallis test or one-way analysis of variance (ANOVA). P-values lower than 0.05 were considered to be significant. For all tests, three independent replicates ( $n = 3$ ) were used respectively. Specific information on the statistical procedures used can be found in the respective figure legends.

### **3 Results - Part 1:**

**Miuraenamide A, a novel actin stabilizing compound, selectively inhibits cofilin binding to F-actin**

### **3.1 Miuraenamide A induces actin nucleation and polymerization, as well as stabilization of filaments**

Based on previous findings[38], we investigated the molecular mechanism of the interaction of miuraenamide A with actin alone. First, we examined the effect of Miuraenamide A on the actin polymerization process in a pyrene assay. With 1  $\mu$ M Miuraenamide A, actin nucleation and polymerization were faster (Fig. 3.1A) but, interestingly, peak fluorescence was lower. This might result from substrate consumption by the rapid formation of small actin aggregates. Monitoring actin filament assembly by TIRF microscopy showed that Miuraenamide A increased the overall rate of formation of actin filaments (Fig. 3.1B). This increase in the number of filaments formed over time suggested a stabilizing effect during nucleation.

Next, we investigated the influence of Miuraenamide A on the rate of actin filament elongation using TIRF microscopy. In the absence and presence of 250 nM of Miuraenamide A, we monitored the length of individual filaments as a function of time and found that the elongation rate doubled compared to control samples (Fig. 3.1C). To determine whether Miuraenamide A plays any role in stabilizing actin filaments, we monitored the disassembly of labeled actin filaments in the presence and absence of 5  $\mu$ M Miuraenamide A by TIRF microscopy. As expected, the length of actin filaments decreased in a time-dependent manner in the absence of Miuraenamide A. In the presence of Miuraenamide A, disassembly of filaments was retarded (Fig. 3.1D). These results indicate that the binding of Miuraenamide A promotes both, the assembly and stabilization of actin filaments.

**Figure 3.1 Miuraenamide A enhances actin polymerization and nucleation, and inhibits depolymerization**

(A) The pyrene assay shows an accelerated polymerization of actin after treatment with Miuraenamide A. (B) The TIRF assay shows increased number of filaments indicating more nucleation of actin upon addition of Miuraenamide A. (C) Actin elongation measured using TIRF microscopy. Left panel: Representative time series of fluorescence images show the elongation of actin filaments. Right panel: The calculated actin elongation rate. (D) Miuraenamide A reduces actin depolymerization as shown by TIRF microscopy. Left panel: Representative fluorescence images at different time points during F-actin depolymerization. Right panel: The average length of actin filaments was quantified as depolymerization parameters. Scale bars in (B) and (D) represent 15 μm.

Scale bar in (C) represents 5  $\mu\text{m}$ . (Kruskal–Wallis test with Dunn’s test as post hoc,  $^{**}P<0.01$  vs. control,  $n=3$ ).

## **3.2 Miuraenamide A competes with phalloidin for binding to F-actin**

Phalloidin is a well-known F-actin stabilizing compound with a well characterized binding site[49]. To investigate whether Miuraenamide A binding to actin competes with phalloidin binding, we performed a competition assay with rhodamine-labeled phalloidin. Rhodamine-labeled phalloidin could be displaced from actin filaments by Miuraenamide A in a concentration dependent manner (Fig. 3.2A) with an IC 50 of about 5 nM (Fig. 3.2A-right panel). This indicates that Miuraenamide A may share a proximal binding site with phalloidin on F-actin, or that Miuraenamide A allosterically influences binding of phalloidin.

## **3.3 Effect of Miuraenamide A on actin filament branch formation**

Subsequently, we measured the effects of Miuraenamide A on actin filament dynamics, which is more complex but also more physiologically relevant. First, we studied Arp2/3-mediated actin filament nucleation. The actin-related protein Arp2/3 complex is a key actin filament nucleation factor that binds to actin and rapidly assembles distinctive branched filament networks. Addition of Miuraenamide A enhanced the overall polymerization in the presence of activated Arp2/3 (i.e. Arp2/3 in complex with the VCA domain of the WAVE protein) (Fig. 3.2C, upper panel). To visualize the effect of Miuraenamide A on actin Arp2/3-mediated branch formation, we used TIRF to measure Atto488 labeled actin in the presence of Arp2/3 (activated by the VCA domain of the WAVE protein). The formation of branched filament networks is accelerated by an increasing concentration of Miuraenamide A (500 nM, 1  $\mu\text{M}$ ). At 5  $\mu\text{M}$  Miuraenamide A, a large number of actin nuclei were observed with very few branches (Fig. 3.2B, bottom panel). We made a similar observation in the pyrene assay: in the presence of 50 mM potassium, actin steadily polymerized, resulting in a linear growth curve. Addition of Arp2/3 complexes induced a sigmoidal curve of nucleation and polymerization. In the presence of an excessive concentration of Miuraenamide A (50  $\mu\text{M}$ ), the onset of actin nucleation was so fast that it could not be substantially accelerated by the addition of Arp2/3 complexes (Fig. 3.2C, lower panel).

**Figure 3.2 Miuraenamide A competes with phalloidin for binding to F-actin and increases branch formation induced by Arp2/3 and CST-VCA**

(A) Miuraenamide A competes with phalloidin binding to actin filaments. Labeled F-actin was incubated with 16.5 nM rhodamine phalloidin and increasing concentrations of Miuraenamide A. Images of actin filaments were taken by TIRF microscopy. Left panel: TIRF images showing the Atto488-labeled actin filaments (upper panels) and rhodamine-labeled phalloidin (lower panels). At increasing concentrations of Miuraenamide A, the binding of phalloidin to actin filaments decreased. Right panel: The IC<sub>50</sub> of Miuraenamide A was calculated (n=3). (B) Actin branch formation was triggered by addition of the Arp2/3 complex and GST-VCA during polymerization, and the process of branch formation was measured using TIRF microscopy. The representative time series of fluorescence images show actin branch formation. Red inserts: zoom-ins of single actin nuclei at 2 $\times$  magnification. (C) The results of pyrene assays show the fast nucleation induced by 5  $\mu$ M Miuraenamide A and Arp2/3/VCA. Scale bar in A and B represents 15  $\mu$ m.

### **3.4 Miuraenamide A inhibits proliferation of endothelial cells at nanomolar concentration and leads to actin aggregation**

To assess the effect of Miuraenamide A on cells, we first measured proliferation. At nanomolar concentrations, Miuraenamide A inhibited the proliferation of HUVEC cells with an IC<sub>50</sub> value of around 9 nM (Fig. 3.4A), which is comparable to that in tumor cell lines (HCT116, HepG2, HL-60, U-2OS)[41]. Phalloidin staining of F-actin revealed that one hour of incubation with 30 nM of Miuraenamide A reorganizes the actin cytoskeleton into clusters or aggregates (Fig. 3.4B). At 100 nM Miuraenamide A, the actin cytoskeleton was completely destroyed and perinuclear actin aggregates were observed (Fig. 3.4B).

### **3.5 Miuraenamide A inhibits HUVEC cell migration**

To examine the effect of Miuraenamide A on the ability of cells to migrate, we performed a scratch assay. The migration of HUVEC cells was inhibited by Miuraenamide A in a concentration-dependent manner with an IC<sub>50</sub> of approximately 80 nM (Fig. 3.4C). Since migration normally occurs in a gradient of growth factors, we studied the effect of Miuraenamide A on the chemotactic properties of HUVECs. In a 2D-chemotaxis assay, the directed migration of HUVECs was inhibited by 10 nM Miuraenamide A, as seen by the reduction of the forward migration index (FMI) and directness, while the mean velocity of movement was not affected (Fig. 3.4D). In 3D-chemotaxis, at 10 nM Miuraenamide A, cell migration directness, mean velocity and FMI were all significantly reduced (Fig. 3.4E). These results indicate that Miuraenamide A has an overall effect on both cell motility and directionality of the movement, both in a simple 2D and in more physiological 3D environments. The reduced velocity in the 3D system could be explained by the cells having a reduced ability to squeeze through a small meshwork.

Overall, the cellular response to Miuraenamide A was typical for actin nucleating compounds[50].

**Figure 3.3** Miuraenamide A inhibits proliferation of HUVEC cells, induces actin aggregation and inhibits migration

(A) Half inhibitory concentration (IC 50) on proliferation of Miuraenamide A (n=3). (B) HUVEC cells were treated with the indicated concentrations of Miuraenamide A for 1 h, fixed and stained for F-actin (red) and DNA to highlight the nuclei (blue). Representative images out of 3 independent experiments performed in triplicates are shown. The upper scale bar in (B) represents 75  $\mu\text{m}$ , and the lower scale bar represents 30  $\mu\text{m}$ . The white frame indicates the zoomed in area. (C) Confluent HUVECs were scratched and treated with Miuraenamide A (indicated concentrations). After 16 h, images were collected and the cell covered area was analysed. Left panel: the measured IC 50 of Miuraenamide A from a scratch assay is shown (n=3). Right panel: Representative images of the scratch assay. The scale bar represents 200  $\mu\text{m}$ . Miuraenamide A inhibits endothelial cells migration (D) in 2D- and (E) in 3D-chemotaxis assays. Quantitative evaluation of the parameters X-Forward migration index, directness and mean velocity are shown (n=3). Analysis of one representative experiment (out of triplicates in three independent experiments) is shown. (Kruskal– Wallis test with Dunn’s test as post hoc, \* $P < 0.05$ , \*\* $P < 0.01$  vs. control, n=3).

### **3.6 Effect of Miuraenamide A on HUVECs tube formation**

To study the effect of Miuraenamide A on a morphogenetic process in vitro, a tube formation assay on matrigel was performed. The tube structure when compared with control could not be established after 16 – 20 h incubation with increasing concentration of Miuraenamide A (Fig. 3.5A). The maturation of the network, which is characterized by a reduction of branching points, tube loops and tube number, as well as by an increase of tube length in control, did not occur after treatment with 10 nM and 30 nM Miuraenamide A (Fig. 3.5B). Treatment led to a fragmented phenotype of the tubular network with a higher number of shorter tubes. At 100 nM Miuraenamide A, HUVEC cells could not build a network at all, the cell-cell contacts were clearly disrupted. Thus, Miuraenamide A interferes with the stability of tubes and development of cell-cell contacts.

**Figure 3.4 Miuraenamide A disturbs tube maturation of endothelial cells on Matrigel**

HUVECs were seeded on matrigel, treated with the indicated concentration of Miuraenamide A respectively and incubated for 16 h. Images were taken and analyzed. (A) Representative images in one experiment (out of triplicates in three independent experiments each) are shown. Cell covered areas recognized by software are indicated in blue, tubes are indicated in pink, and loops are indicated by yellow numbers. (B) Tube length, number of total loops, total tubes, and total branching points were analyzed ( $n=3$ ). The scale bar represents 30  $\mu\text{m}$ . (One-way ANOVA with Tukey post hoc test for multiple comparisons,  $*P<0.05$  vs. control,  $n=3$ ).

### 3.7 Effect of Miuraenamide A on the binding of proteins to G-actin

We next investigated whether Miuraenamide A affects the binding of ABPs to G-actin. To this end, we performed pulldown experiments with G-actin immobilized on beads and added single ABP (gelsolin, profilin, cofilin or Arp2/3 complex with GST-VCA). As depicted in Fig. 3.6A-D, the total amount of the tested ABPs in G-actin pellets did not increase or decrease even if treated with a high amount of Miuraenamide A (10 or 100-fold excess), indicating that Miuraenamide A does not compete with gelsolin, profilin, cofilin or Arp2/3 complex for binding to G-actin.

**Figure 3.5 Miuraenamide A does not change the binding of ABPs to G-actin**

G-actin beads were incubated with indicated concentrations of Miuraenamide A for 30 min at room temperature, then 0.01mg/ml of the G-actin binding proteins (A) gelsolin, (B) profilin, (C) cofilin and (D) Arp2/3 complex & GST-VCA was added respectively and incubated for 1 h at room temperature. After 1 h, the mixture of actin beads and ligands was spun and only the ligands bound to G-actin will be co-precipitated in the pellet. The amount of G-actin binding protein in the pellets was quantified. Representative images of protein bands and quantifications are shown. (Kruskal–Wallis test with Dunn’s test as post hoc, no significant differences vs. control, n=3).

### **3.8 In contrast to jasplakinolide, Miuraenamide A influences cofilin binding to F-actin**

To investigate potential competition of Miuraenamide A and ABPs for binding to F-actin, we also performed a binding assay with cofilin, gelsolin and Arp2/3 complex (together with GST-VCA) to F-actin. In the absence of Miuraenamide A, cofilin was largely found in the F-actin pellet (Fig. 3.7A), as expected from the known interaction between cofilin and F-actin. In the presence of Miuraenamide A, a significant reduction of cofilin was observed in the pellet (Fig. 3.7A, upper panel). Jasplakinolide did not change binding of cofilin to F-actin, even when added at a ten-fold concentration in comparison to Miuraenamide A. (Fig. 3.7A, lower panel). Neither Miuraenamide A, nor jasplakinolide influenced binding of gelsolin (Fig. 3.7B), and Miuraenamide A did not affect Arp2/3 complex binding to F-actin, since the amounts of Arp2/3 complex in F-actin pellet were similar in the presence or absence of Miuraenamide A (Fig. 3.7C). These results suggest that Miuraenamide A selectively interferes with the binding of cofilin to F-actin, and that this action is specific for Miuraenamide A, since it was not mimicked by jasplakinolide.

*(A) Miuraenamide A inhibits binding of cofilin to F-actin filaments (upper panel), while jasplakinolide does not (lower panel). F-actin was incubated with (A) cofilin, (B) gelsolin or (C) Arp2/3 complex & GST-VCA, together with Miuraenamide A or jasplakinolide (molar ratio 1:10). Binding of gelsolin (B) or Arp2/3 (C) to F-actin were not influenced by Miuraenamide A or jasplakinolide. The amount of F-actin binding protein in the total sample, supernatant and pellets was quantified. Representative images of protein bands and quantifications are shown. (Kruskal–Wallis test with Dunn’s test as post hoc, \*\* $P < 0.01$  vs. control,  $n=3$ ).*

## **4 Results - Part 2:**

**Chivosazole A modulates protein-  
protein-interactions of actin**

#### **4.1 Chivosazole A sequesters G-actin, inhibits actin nucleation, polymerization and branch formation and destabilizes F-actin in vitro**

To characterize the functional effects of chivosazole A in comparison with a prototypic actin depolymerizer with a different binding site and mode of action (latrunculin B), we performed a pyrene assay with pyrene labeled actin and TIRF assay with Atto488 labeled actin. In the pyrene assay, chivosazole A concentration dependently inhibits actin polymerization (Fig. 4.1A), as previously described by others[44]. When investigating the underlying mechanisms, we found that the critical concentration of actin in the presence of either latrunculin B or chivosazole A, was increased to a similar degree (Fig. 4.1B). This indicates a similar sequestering action of both compounds. Accordingly, we found a decreased nucleation of actin in TIRF assays (Fig. 4.1C), and a lower rate of polymerization (Fig. 4.1D). In addition, we observed a destabilizing effect of chivosazole A on F-actin filament stability (Fig. 4.1E). In addition, we observed the formation of branched filament networks triggered by Arp2/3 complex and GST-VCA. Branches formed slower and shorter with 5  $\mu$ M chivosazole A (Fig. 4.1F). Taken together, our data suggest that chivosazole A inhibits actin filament branch formation by sequestering G-actin, so that less actin nuclei were formed for forming actin filament branches.

**Figure 4.1 Chivosazole A sequesters G-actin, inhibits actin nucleation, polymerization and branch formation and destabilizes F-actin in vitro**

(A) Chivosazole A inhibits polymerization of pyrene actin concentration dependently. (B) Chivosazole A (20  $\mu$ M) and Latrunculin B (positive control, 20  $\mu$ M) shift the critical concentration of actin for polymerization to a similar degree. (C) and (D) In TIRF assays, chivosazole A inhibits nucleation of actin and the elongation rate. (E) F-actin filaments are destabilized by chivosazole A in the TIRF assay. (F) Actin branch formation is triggered by addition of the Arp2/3 complex and GST-VCA during polymerization, and the process of branch formation is inhibited by chivosazole A. The representative time series of fluorescence images are shown. Red inserts in (F): Zoom-ins of single actin nuclei at 2 $\times$  magnification. Scale bars in (C), (E) and (F) represent 15  $\mu$ m. Scale bars in (D) represents 5  $\mu$ m. Data are presented as mean  $\pm$  SEM,  $n = 3$ ,  $*p < 0.05$  using Kruskal-Wallis test.

**4.2 Chivosazole A inhibits proliferation and changes actin architecture in endothelial cells**

In order to get insights into potential functional differences between the two compounds (in spite of their similar actions on actin alone), we performed comparative experiments on a cellular level. In HUVECs chivosazole A inhibited proliferation with an IC<sub>50</sub> of approximal 3 nM. This is in good accordance with previously published values in different mammalian cells[44], and demonstrates chivosazole A to be much more potent than latrunculin B (Fig. 4.2A). Morphologically, chivosazole A causes dissociation of F-actin fibers and formation of amorphous actin aggregates with increasing concentrations (Fig. 4.2B).

**Figure 4.2 Chivosazole A inhibits proliferation and changes actin architecture in endothelial cells**

(A) Chivosazole A (left panel) inhibits HUVEC cells proliferation much more potently than latrunculin B (right panel). (B) The actin cytoskeleton of HUVECs is rapidly rearranged by chivosazole A. Representative images in one experiment (out of triplicates in three independent experiments each) are shown. Lower panel: Zoom-in of the white frames indicated as boxes in the upper panels. Blue: nuclei stained with Hoechst, red: F-actin stained with rhodamine-phalloidin. Scale bars: 75  $\mu\text{m}$  (upper panel), 30  $\mu\text{m}$  (lower panel).

### 4.3 Chivosazole A inhibits HUVEC cell migration

Since cellular motility is a central aspect of actin function, we investigated the effects of the two compounds on migration of HUVECs in a scratch assay and specifically on directional migration (chemotaxis). The IC 50 value concerning migration was 10-fold higher than for proliferation (Fig. 4.3A). This is most likely due to the shorter duration of the migration assay (16 h vs. 72 h). With latrunculin B the difference in potency in comparison to chivosazole A was less in migration than in proliferation, indicating that latrunculin B loses potency over time more rapidly than chivosazole A. In 2D-chemotaxis assay, overall features of cell motility (velocity), and directional components of migration were assessed. Both

compounds caused a decrease of cell velocity, and, additionally, a loss of the “sense of direction” (Fig. 4.3B).

**Figure 4.3 Chivosazole A inhibits migration in endothelial cells**

(A) Upper panel: Dose response curves of cell migration after treatment with chivosazole A or latrunculin B in a scratch assay. Lower panel: representative images of scratches after migration. Scale bar: 200 μm. (B) In 2D-chemotaxis assay, quantitative evaluation of the parameters X-Forward migration index, directness and mean velocity are shown. Analysis of one representative experiment

(out of triplicates in three independent experiments) is shown. Data are presented as mean  $\pm$  SEM,  $n = 3$ , \* $p < 0.05$ , \*\* $p < 0.01$  using Kruskal-Wallis test.

#### 4.4 Chivosazole A disturbs tube formation in endothelial cells

To study the effect of chivosazole A on a morphogenetic process in vitro, a tube formation assay on matrigel was performed. The tube structure when compared with control could not be established after 16 – 20 h incubation with either chivosazole A or latrunculin B (Fig. 4.4). Treatment led to a fragmented phenotype of the tubular network with a higher number of shorter tubes. The cell-cell contacts were disrupted. Thus, chivosazole A has same effect as latrunculin B, interfering with the stability of tubes and development of cell-cell contacts.

**Figure 4.4 Chivosazole A disturbs tube formation in endothelial cells**

(A) HUVECs were seeded on matrigel, treated with the indicated concentration of chivosazole A and latrunculin B respectively and incubated for 16 h. Images were taken and analyzed. Representative images in one experiment (out of triplicates in three independent experiments each) are shown. Cell covered areas recognized by software are indicated in blue, tubes are indicated in pink, and loops are indicated by yellow numbers. The scale bar represents 30  $\mu$ m.

#### 4.5 Chivosazole A competes with ABPs for binding to G-actin and causes dimerization of actin

Based on the surprising functional differences between the two compounds concerning transcription (Table S6, S7 and S8), and the fact that actin influences transcriptional regulation mainly by its interaction with ABPs, we tested the effects of the two compounds on the binding of several proteins (cofilin, gelsolin and profilin) to G-actin. We performed an actin pull-down assay with G-actin immobilized on beads and single ABPs in the absence and presence of chivosazole A or latrunculin B, then quantified the ABP binding to G-actin.

As seen in Fig. 4.5A-C (left panels), the total amount of the tested ABPs in G-actin pellets decreased with chivosazole A (molar ratio 1:100), indicating that it prevented binding of cofilin, gelsolin and profilin to G-actin. In contrast, latrunculin B had no such effect (Fig. 4.5A-C, right panels), which offers a potential explanation for the functional differences between these two compounds.

A

B

C

**Figure 4.5 Chivosazole A prevents the binding of ABPs to G-actin, while latrunculin B does not**

*G-actin beads were pretreated with indicated concentrations of either chivosazole A or latrunculin B for 30 min at room temperature, then co-incubated with the G-actin binding proteins (A) cofilin, (B) gelsolin or (C) profilin at a molar ratio of 100:1 (compound: ABP). After 1 h, the mixture of actin beads and ligands was spun and only the ligands bound to G-actin will be co-precipitated in the pellet. The amount of ABP in pellet was quantified. Representative images of protein bands are shown. Data are presented as mean  $\pm$  SEM,  $n = 3$ ,  $*p < 0.05$ ,  $**p < 0.01$  using Kruskal-Wallis test.*

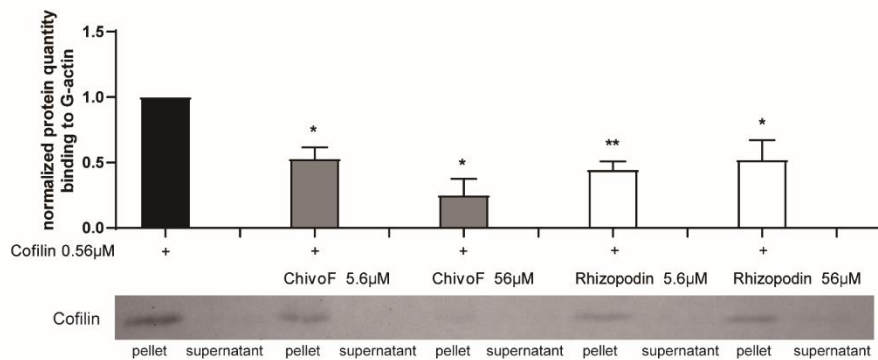

Since the binding affinity of thymosin  $\beta 4$  is very weak, and we were not able to detect this protein in the pull-down assay, we crosslinked the bound protein as previously described[51]. With crosslinking, a 1:1 complex of thymosin  $\beta 4$  with G-actin at approximately 47.5 kDa is detectable (Fig. 4.6A, left panel). Chivosazole A reduced crosslink product formation (Fig. 4.6A, right panel). In addition, a high molecular weight complex (approximately 100 kDa) was formed in the presence of chivosazole A (Fig. 4.6A, left panel and also in the absence of thymosin  $\beta 4$ , Fig. 4.6C), suggesting the formation of G-actin dimers. Latrunculin B decreased the formation of the thymosin  $\beta 4$ /G-actin complex (Fig. 4.6B), but did not cause formation of actin dimers. Gel filtration experiments also showed an increase of actin dimers in the presence of chivosazole A under conditions of a different pH (Fig. 4.6D, experiments were performed by Dr. Sabine Schneider, Department of Chemistry, Technical University of Munich, Germany). However, the retention time of these dimers differs from that of spontaneously formed physiological dimers, indicating a different structure (Fig. 4.6D).

shown. (D) Size-exclusion chromatography at different pH values indicate the formation of actin-dimers in the presence of chivosazole A. Dimers formed spontaneously in the absence of chivosazole A elute at a time point different from the drug induced ones, hinting at an unphysiological conformation of the latter ones. Results of size-exclusion chromatography in (D) are provided by Dr. Sabine Schneider, Department of Chemistry, Technical University of Munich, Germany. (Data are presented as mean  $\pm$  SEM,  $n = 3$ ,  $*p < 0.05$  using Kruskal-Wallis test)

Chivosazole F, a derivative which is structurally very similar to chivosazole A, and rhizopodin, an also structurally related compound, inhibited binding of profilin, gelsolin and cofilin to G-actin to a similar degree as chivosazole A (Fig. 4.7).

## **5 Discussion**

## **5.1 Actin targeting compounds: promising biological tools and therapeutic options**

Actin is the most abundant protein in eukaryotic cells and the protein with the greatest variety of binding partners[3, 52, 53]. Due to its ubiquitous expression and its many biological functions, actin has not been pushed as a clinically relevant drug target. Especially the question how selective functional effects could be elicited by just increasing or decreasing overall actin polymerization by the use of small molecular binders has precluded the use of actin targeting natural compounds in a therapeutic setting for many years in spite of their availability[28, 30, 54]. In recent years, however, it has become increasingly clear that actin-binding proteins (ABPs) are the key to localized and specific regulation of actin polymerization and depolymerization. For example, it has been shown that JMY or WHAMM are needed to localize actin nucleation specifically to the autophagosome[55, 56]. Since the amount of G-actin in a cell is limited, a competition between actin monomers, F-actin filaments, and ABPs for binding to the available G-actin pool takes place, and turns out to be relevant for regulation of actin function[31, 52, 57]. Exploiting this level of regulation by using the concept of “biomolecular mimicry”[34, 58] would open a new field of biological tools or even therapeutic options by developing novel and much more specific actin targeting compounds.

## **5.2 Miuraenamide A, a novel actin stabilizing compound, selectively inhibits cofilin binding to F-actin**

### **5.2.1 Miuraenamide A, an actin stabilizer, and its specific mode of binding**

Miuraenamide A has been discovered in 2006 with high cytotoxicity to a range of tumor cell lines[41]. It is presumed to be an actin filament stabilizing agent[38]. The absolute stereostructure of miuraenamide A was determined soon in 2008[40]. Comparable biological effects were observed with other cyclodepsipeptides, such as chondramide[42] and jasplakinolide[35], which is not surprising on the basis of their closely related structure (Fig. 1.1). However, it is still poorly characterized and its influence on actin is still not clear. In this study, we have performed an in-depth characterization of miuraenamide A. The in vitro data on isolated actin indicate that miuraenamide A has a profile similar to phalloidin or jasplakinolide (increase of nucleation, enhanced polymerization, and stabilization). FCS assay result suggests that miuraenamide A favors polymerization by stabilizing the early

stage oligomers formed during nucleation (Fig. S1 and Fig. S2). This reveals the increasing nucleation and elongation effect of miuraenamide A in TIRF assay (Fig. 3.1). The competition with phalloidin for actin binding in the TIRF assay indicates binding sites of both compounds in close proximity (Fig. 3.2A).

To get an impression of the specific binding mode of miuraenamide A, we performed *in silico* studies (experiments were performed by the group of Prof. Iris Antes, Protein Modelling group, Technical University of Munich, Germany), which revealed that miuraenamide A binds to motifs similar, but different to the binding site of phalloidin, chondramide, or jasplakinolide[59-61]. Interaction of a compound with F-actin is complex, since the compound may bind to three actin molecules at the same time at different sites. For the sake of simplicity, we collapsed all binding sites of miuraenamide A, phalloidin and jasplakinolide on one actin monomer, respectively (Fig. S3). This simulation reveals that M4 is a binding site which miuraenamide A shared with phalloidin and jasplakinolide, which in part explains the competition of Miuraenamide A with phalloidin. M2 and M5 also show similar binding sites as phalloidin and jasplakinolide, but M1 and M3 address sites on the actin molecule, which are not bound by phalloidin or jasplakinolide. The mode of binding to M1 is unique in that the bromophenol substitution of the macrocycle and the three aromatic residues from actin (Tyr133, Phe352, and Tyr143) form an aromatic cyclic tetramer (Fig. S4A and B). Similar motives (involving more or less aromatic cycles) were shown to be frequently observed in proteins and contribute to the stabilization of their tertiary structure[62-64]. They were also recently identified as a key feature of metal centered cycloadducts[65]. This relatively strong interaction reveals the importance of the bromophenol ring as a crucial moiety of the macrocyclic miuraenamide A. The second phenyl ring bound to the macrocycle, on the other hand, is not engaged in any crucial interactions.

Analysis of the influence of miuraenamide A binding on the F-actin filament structure by simulation of actin-trimer complexes with and without bound miuraenamide A showed that the binding of miuraenamide A influences the overall structures of the actin trimer, as for the apo-actin-trimer a different relative arrangement of the individual actin monomers was observed compared to the holo-trimer complex (Fig. S4C, D, E and F). A more detailed analysis of the structures (Fig. S4G and Fig. S5A) reveals that the miuraenamide A ligand bound to the actin DNase I binding site triggers the migration of the D-loop in monomer 3 towards actin. This phenomenon increases the contact area between the monomers. Presumably miuraenamide A further acts as a buffer between these two monomers and stabilizes the compact trimer form. Comparisons between holo- and apo-structures show

that the interaction between monomers 2 and 3 is affected most by the binding of miuraenamide A (Fig. S4D, F, blue lines), although all monomers contain a ligand in the holo-system. This is consistent with the fact that only the ligand of monomer 2 is located at an inter-monomeric interface in the trimer simulation. This observation, together with the RMSD analysis, further highlights that the binding of miuraenamide A does not affect the individual integrity of the units but regulates the inter-monomeric interactions. Overall, miuraenamide A binding ensures a tighter and stronger packing of the actin monomers compared to the apo F-actin (Fig. S4H) by shifting the D-loop, which is indispensable for F-actin stabilization[59].

### **5.2.2 Miuraenamide A has comparable effect on a cellular level as other actin stabilizer, but has a unique selectivity inhibition on cofilin binding to F-actin**

To find out, whether this unique binding mode results into a different functional outcome, we investigated miuraenamide A also on a cellular level. Miuraenamide A had functional effects similar to chondramide, another actin nucleator (inhibition of proliferation, migration), and also the morphological changes were comparable[42, 66].

Since the hydrophobic cleft in the actin molecule, where M1 is situated, is the main hub for interaction of actin with other proteins, we analyzed interactions of ABPs with both, G- and F-actin. Interactions of ABPs with G-actin were not altered by miuraenamide A. Obviously, the compound does not bind to a single monomeric actin, or it does not directly interfere with protein binding. In contrast, we observed that miuraenamide A inhibited ABP cofilin binding to F-actin. The interesting point here is that this observation was specific for cofilin – the binding of gelsolin or the Arp2/3 complex on F-actin were not affected. Even more interestingly, jasplakinolide did not have this effect. Consequently, the action of miuraenamide A seems to be due to its unique binding mode. Our molecular dynamics (MD) simulations offer an explanation for the inhibition of cofilin binding to F-actin by miuraenamide A: the shift of the D-loop by miuraenamide A leads to a clash between this loop and cofilin in its bound conformation (Fig. S5B).

It has already been sporadically described that actin binding compounds are able to influence binding of ABPs to G- or F-actin (e.g. cytochalasin D and MRTF[33, 67], or phalloidin and gelsolin[68]). Obviously, these small molecules can act as inhibitors of protein-protein interactions, and afford a certain specificity.

On a functional cellular level, the comparison between jasplakinolide and miuraenamide A was quite astounding. Though migration and proliferation were inhibited by miuraenamide A as was to be expected, the differences of transcriptional regulation in HUVEC cells after

treatment with both compounds were pronounced: 101 genes were regulated in a significantly different way (Table S1 and S3). When the regulated genes are classified into functionally relevant gene ontologies (Table S4 for Miuraenamide A and Table S5 for jasplakinolide), it becomes clear that most of the differences between Miuraenamide A treatment and jasplakinolide do not result from different extents of regulation of the same genes, but from regulation of different sets of genes (Table S2). This might be linked to the effects of miuraenamide A on binding of cofilin to F-actin (Fig.5.1), since cofilin directly modulates nuclear architecture[69], but also plays an important role in regulating nuclear actin levels[70], which, in turn, have an influence on transcriptional regulation[71]. However, due to the complexity of the role of actin and ABPs in transcriptional regulation, we cannot rule out other modes of action of miuraenamide A treatment.

**Figure 5.1 MiuA prevents cofilin binding to F-actin**

## 5.3 Chivosazole A modulates protein-protein-interactions of actin

### 5.3.1 Is chivosazole A just another of many known natural compounds, which interfere with actin polymerization dynamics?

Chivosazole A has been initially described as cytotoxic agent in eukaryotic cells in 1995[43], and its absolute configuration has been resolved 12 years later[45]. Its actin interfering effects (inhibition of G-actin polymerization and depolymerization of F-actin) were identified 2009[44]. One could argue that chivosazole A is just another of many known natural compounds, which interfere with actin polymerization dynamics[72]. However, it turned out that each of these actin binding compounds has unique functional features, and that it is worthwhile to study their structure-activity-relationships.

Very recently, chivosazole F, a compound closely related to chivosazole A has been shown to directly interact with actin by chemoproteomics[73]. Based on genome-wide mutagenesis studies in yeast with chivosazole F it was proposed that the binding site for chivosazole F on actin would partially overlap the binding site for latrunculinA in the ATP-binding cleft [73]. However, here we present a crystal structure of an actin- ChivoA complex, revealing that it binds at the barbed end of actin, and not to a site close to the latrunculin A binding site. This discrepancy could be explained by the fact that we used chivosazole A, while chivosazole F was used in the other work. However, this seems unlikely, as both compounds are nearly identical (Fig. 1.2). It is feasible that the sequence of actin (which is evolutionary highly conserved) lacks flexibility, and mutations at the real binding site just do not yield functional protein. The described mutations (R183K and R335K) might have allosteric consequences, influencing binding of chivosazole F at a distant site[73].

In order to elucidate the previously unknown binding mode of chivosazole A to actin, we first determined the X-ray crystal structure of chivosazole A in complex with G-actin to 2.4 Å resolution (experiments were performed by Dr. Sabine Schneider, Department of Chemistry, Technical University of Munich, Germany). Chivosazole A binds to the barbed end (target binding cleft) of G-actin (Fig. S6A and Fig. S7). This binding site for chivosazole A is very close, but not identical to those of many actin binding macrolides (Fig. S6B): Despite the variation in ring size and decoration of the tail with different backbone substitutions present in actin-binding macrolides, they possess a common theme in their interaction with actin. In all reported actin complex-structures the macrolactone ring binds to subdomain 1, with the side chain/tail protruding into the hydrophobic cavity between subdomain 1 and 3[34, 74-81]. The oxazole ring of chivosazole A occupies an intermediate

position compared to the trisoxazole rings of jaspisamide A, kabiramide C and ulapulaide A[34, 81] (Fig. S6B). Albeit we cannot rule out that crystal lattice contacts impact on the binding mode of chivosazole A (Fig. S7), for jaspisamide A and kabiramide C identical interactions with actin were observed in structures obtained from different crystal symmetries.

Interestingly, the binding side of chivosazole A overlaps with that for a number of actin-binding proteins (ABPs). This might explain, why chivosazole A competes with cofilin, gelsolin, profilin or thymosin  $\beta$ 4 for binding to G-actin, while latrunculin B does not. These proteins interact with actin by insertion of an amphiphilic helix into the target binding cleft as depicted in Fig. S8 [82-86].

Recently the cryo-EM structure of F-actin has been reported (PDB code 6BNO[87]), revealing an interface of 1,076 Å<sup>2</sup> between the actin-monomers (theoretical gain of free energy of -6.9 kcal/mol). Here the D-loop (residue 40-50) slides into the target binding cleft between subdomain 1 and 3. Superposition of the F-actin structure and the actin-ChivoA complex shows that the ChivoA-tail partly occupies the binding site for the DNase-binding loop (Fig. 6C), and, in addition, slightly perturbs other structural elements involved in actin-actin interaction (Fig. S6C). This explains the F-actin-severing effect of chivosazole A, which does not occur with rhizopodin or cytochalasin D, other actin binding polyketides[44, 88]. Albeit actin-ChivoA complexes can still form dimers in vitro, their overall shape differs from that of physiological actin-dimers in solution as indicated by size-exclusion chromatography (Fig. 4.6D). The occurrence of actin dimers has already been described with rhizopodin and swinholide A[78, 80]. However, these compounds have two enamide side chains each, which explain their crosslinking activity, while chivosazole A has just one. It has recently been shown that the induction of unphysiological actin oligomers by toxins can cause dramatically altered affinity towards ABPs[89]. This effect could further contribute to the higher efficacy of chivosazole A in comparison to latrunculin B.

### 5.3.2 Chivosazole A selectively competes with ABPs

Chivosazole A has been previously described to inhibit actin polymerization and to induce F-actin depolymerisation[44]. In our work, we corroborate this finding, and additionally show that nucleation is inhibited and G-actin is sequestered in a similar way as with latrunculin B. This makes it understandable that at first glance both compounds have similar functional effects on eukaryotic cells (proliferation, migration, cytoskeletal architecture), which can be explained by an overall disturbance of actin turnover. However, when having a closer look at binding of ABPs to G-actin, as discussed above, we see striking differences between

both compounds, and a high selectivity: profilin, gelsolin and cofilin compete only with chivosazole A (Fig.5.2), while chivosazole A and latrunculin B both compete with thymosin  $\beta$ 4. Influencing these interactions might have distinct consequences on downstream signaling, and ultimately on gene expression. Indeed, we see the differences of chivosazole A and latrunculin B on gene expression in endothelial cells: a number of genes that are only up- or downregulated by chivosazole A and not by latrunculin B, and vice versa (Table S6, S7 and S8).

**Figure 5.2 ChivoA prevents ABPs binding to G-actin**

Consequently, our result reveals a previously unexpected layer of complexity in the mechanism of action of actin binding compounds: instead of just causing bulk stabilization or de-stabilization of actin fibers, distinct cellular functions could be preferentially addressed by single compounds. “Biomolecular mimicry”[58], the fact that compounds can selectively compete with ABPs, and the high structural diversity of actin binding compounds might team up to generate an unprecedented functional selectivity for pharmacologically targeting actin. Since the total synthesis of chivosazole F has been resolved[46], and chivosazoles can be produced biotechnologically, these compounds might be ideal candidates for derivatization and for exploring structure-activity-relationships with actin.

## 5.4 Summary and conclusion

In our work we show that

- Miuraenamide A has cellular effects and actin stabilizing effect in vitro comparable to jasplakinolide, owing to their closely related structure,
- Chivosazole A has cellular effects and actin destabilizing effect in vitro similar to latrunculin B.

**Figure 5.3 Effect of actin binding compounds on actin dynamics**

*Miuraenamide A induces actin nucleation, polymerization and stabilizes F-actin. Chivosazole A destabilizes F-actin, inducing actin depolymerization.*

However, we identified the unique mode of actions of both miuraenamide A and Chivosazole A by structural data that

- Miuraenamide A selectively inhibits binding of cofilin to F-actin and causes transcriptional regulation different from that of jasplakinolide,
- Chivosazole A competes with ABPs for binding to G-actin in contrast to latrunculin B, and influences transcriptional activity in human primary cells in a different manner from latrunculin B.

Consequently, our findings reveal that small structural differences in actin binding compounds can cause functional selectivity (miuraenamide A and jasplakinolide), and the mechanisms of actions of actin binding compounds are much more complex than previously conceived which was not presumed in this class of molecules. The much better synthetic

accessibility of both miuraenamide A and chivosazole A, as compared to other actin binding compounds, makes them ideal candidates for studying structure-activity relationships. Ideally, it could be feasible to rationally create appropriate derivatives with improved activities that do not influence actin polymerization or depolymerization per se, but selectively modulate the binding of single ABP, and circumvent the selectivity issues, which hindered the development of actin-addressing drugs.

## **6 Summary**

## **6.1 Part 1: Miuraenamide A, a novel actin stabilizing compound, selectively inhibits cofilin binding to F-actin**

Actin binding compounds such as phalloidin, jasplakinolide and latrunculin are widely used tools in cell biology regulating actin dynamics. Jasplakinolide is a prototypic actin stabilizer which binds to F-actin with no effect on ABPs (cofilin, gelsolin, profilin). In contrast miuraenamide A, as a new actin stabilizer, competes exclusively with cofilin for binding to F-actin. Notably, the molecular basis for this difference still remains to be determined. To investigate whether this difference is due to a specific binding site in miuraenamide A we performed molecular dynamics simulations. These simulations suggest that the bromophenol group of miuraenamide A interacts with actin residues Tyr133, Tyr143, and Phe352. This interaction shifts the D-loop of the neighboring actin, creating tighter packing of the monomers, and blocks the binding site of cofilin. We found that miuraenamide A shows activity similar to jasplakinolide both in vitro with respect to polymerization, depolymerization, branching, nucleation and in vivo with respect to cell proliferation, migration. However, gene expression in HUVEC cells was differentially affected by both compounds, indicating functional differences. We found that relatively small changes in the molecular structure give rise to this selectivity, suggesting that actin binding compounds might serve as promising scaffolds for creating actin binders with specific functionality instead of just “stabilizers”.

## **6.2 Part 2: Chivosazole A modulates protein-protein-interactions of actin**

Actin is a protein of central importance for many cellular key processes. Its function is regulated by local interactions with a large number of ABPs. To date, various compounds are known either increasing or decreasing polymerization dynamics of actin. However, no actin binding compound has been developed for clinical applications yet, due to selectivity issues. We provide a crystal structure of the natural product chivosazole A bound to actin, and show that – in addition to inhibiting nucleation, polymerization and severing of F-actin filaments – it selectively modulates binding of ABPs to G-actin: while unphysiological actin dimers are induced by chivosazole A, interaction with of gelsolin, profilin, cofilin and thymosin  $\beta$ 4 is inhibited. Moreover, chivosazole A causes transcriptional effects differing from latrunculin B, an actin binder with a different binding site. Thus, our data show that chivosazole A and related compounds could serve as scaffolds for the development of actin binding molecules selectively targeting specific actin functions.

## 8 Appendix

## 8.1 Supplementary Figures

**Figure S 1 Measurement of actin nucleation by Fluorescence correlation spectroscopy (FCS) experiment**

The fluorescence signal of 100 nM actin-atto488 as a function of time after 1h incubation, without (A) and with (B) 10 × excess of Miuraenamide A. (C) FCS curves of 100 nM actin-atto488 with and without Miuraenamide A. Inset: detail of the autocorrelation function at longer timescales showing the formation of larger oligomers with Miuraenamide A. (D) Number of spikes due to filaments diffusing through the observation volume in 10 min time intervals. The data show that up to 6 times more spikes are observed during the course of one hour in the presence of Miuraenamide A. Error bars represent the standard error of the mean of three independent measurements. (Results were provided by Prof. Dr. Don C. Lamb, Department Chemistry, Ludwig-Maximilians University Munich, Germany)

**Figure S 2 Influence of MiuA on the formation of small oligomers of actin**

(A, B) MiuA lowers the critical concentration of actin polymerization. The fluorescence intensity as a function of time is shown for 50 nM atto488 labeled actin after 1h incubation, without (A) and with (B) 10x excess of MiuA. (C) FCS curves of 50 nM actin-atto488 with and without MiuA, the emergence of a slowly diffusing component due to the formation of small oligomers is observed. (D) The Intensity of spikes (in units of the mean count rate) is shown for the respective measurements. Blue squares: 100 nM actin-atto488, red circles: 100 nM actin-atto488 and 1  $\mu$ M MiuA. Error bars represent the standard error of the mean of three independent measurements. After 30 min of incubation, a higher spike intensity is observed for actin in the presence of MiuA. (Results were provided by Prof. Dr. Don C. Lamb, Department Chemistry, Ludwig-Maximilians University Munich, Germany)

**Figure S 3 Binding sites for miuA, phalloidin and jasplakinolide**

Five potential binding sites for MiuA (M1 to M5) obtained by the computer-based docking simulations are projected into the G-actin monomer (Protein Data Bank: 3HBT). G-actin: magenta, respective binding sites of the compounds: yellow. (Data were provided by Prof. Iris Antes, Protein Modelling group, Technical University of Munich, Germany)

**Figure S 4 Structures of the docked Miuraenamides A and after 25 ns of MD equilibration**

A global view of the system is presented in (A) and (B) gives a detailed view of the binding site. Actin is shown in cartoon representation, ADP (blue),  $\text{Ca}^{2+}$  (green) and Miuraenamide A (purple) are shown as van der Waals spheres (A) and as sticks (B). Residues interacting with the ligand are shown with

sticks. (C+D) RMSD time-series (Å) of the apo- (C) and holo- (miuraenamide A bound) (D) simulations. The black, red, magenta, and blue colors represent the deviations of  $\alpha$  carbon atoms of the trimer, monomer1, monomer 2 and monomer 3 from the initial structures, respectively. (E+F) The deviation of the distances of pairs of monomers (based on the center of mass of the stable  $\beta$ -sheet regions of each monomer) from the initial structure as a function of time for the apo- (E) and holo- (F) systems. (G) The orientation of Miuraenamide A within the trimer is depicted with an additional focus on the interaction between the D-loop of monomer 3 and the ligand of monomer 2 in the inset. (H) The difference in packing between the apo- (transparent coloring) and holo- (solid coloring) trimer systems is illustrated for a representative structure of the two complexes. (Data were provided by Prof. Iris Antes, Protein Modelling group, Technical University of Munich, Germany)

**Figure S 5 Conformational changes induced by binding of MiuA**

(A) Once MiuA binds to F-actin, the D-loop of monomer 3 moves closer to monomer 2 during the molecular dynamics simulation. (B) MiuA and cofilin bound to the F-actin (the position of cofilin is shown as bound in the apo-structure with F-actin). The new conformation of the D-loop overlaps with the bound conformation of cofilin. (Data were provided by Prof. Iris Antes, Protein Modelling group, Technical University of Munich, Germany)

**Figure S 6 X-ray crystal structure of G-actin in complex with chivosazole A**

(A) Structure of the actin-chivosazole A complex, overall folding topology and domain structure. The actin is depicted as ribbon, with the four domains highlighted. The ATP (orange) and chivosazole A (green) are shown as stick model, the magnesium ion as sphere (purple). Overlaid, for chivosazole A the simulated annealing Fo-DFc difference electron density is contoured at 2.5 (green). (B) Superposition of actin structures in complex with macrolides. The actin surface is colored according to the surface residue charges and the macrolides are shown as stick models. Chivosazole A (dark green, this work), lobophorolide (light green, PDB code 3M6G), jasplakinolide A (cyan; PDB code 1QZ6) and sphinxolide B (golden; PDB code 2ASO). (C) Mapping of the chivosazole A (green space-fill model) binding side on the surface of the cryo-EM F-actin structure (PDB code 6BNO). Inset: zoom in the F-actin interface (blue) overlaid with the actin-chivosazole A complex (green). The DNase-binding loop (residues 40-50) of subdomain 2 interacting with subdomain 1 is shown in red. (D) Schematic diagram of the interactions between actin and chivosazole A. Hydrophobic interactions are indicated by the red half-circles. The 2D-plot was prepared with LigPlot[90]. (Data were provided by Dr. Sabine Schneider, Department of Chemistry, Technical University of Munich, Germany)

**Figure S 7**

(A) Simulated annealing Fo-DFc difference electron density (contoured at 2.5  $\sigma$ ; green) of Chivo A, with the actin surface coloured according to the surface residue charges. (B) Crystal-lattice contacts at the ChivoA binding site. (Data were provided by Dr. Sabine Schneider, Department of Chemistry, Technical University of Munich, Germany)

**Figure S 8 Comparison of chivosazole A binding site and the interaction interface of actin binding proteins**

(A) cofilin (light pink; PDB code 3J0S), (B) gelsolin (cyan; PDB code 1H1V), (C) MRTF-A (grey, PDB code 2V52), (D) thymosin  $\beta$ 4 (T $\beta$ 4) (golden; PDB code 1T44) and (E) profilin (light green; PDB code 2BTF). The actin is shown as surface representation colored according to the surface charge. ChivoA is depicted as green stick model. The amphiphilic helices of the actin-binding proteins, which pack into the target binding groove, are highlighted in pink. (Data were provided by Dr. Sabine Schneider, Department of Chemistry, Technical University of Munich, Germany)

## 8.2 Supplementary Tables

Treatment	Total number of differentially regulated genes	Number of upregulated genes	Number of downregulated genes
Miuraenamide A (60 nM) vs. control	779	384	395
Jasplakinolide (120 nM) vs. control	224	132	92
Miuraenamide A (60 nM) vs. Jasplakinolide (120 nM)	101	55	46

**Table S 1 Gene regulation by miuraenamide A and jasplakinolide after 4 h**

Treatment of HUVECs with a well-tolerated concentration of Miuraenamide A (60 nM) or and equipotent concentration of jasplakinolide (120 nM) for 4 h caused dramatic effects on transcriptional regulation. Assessment of transcriptome was performed by Prof. Dr. Wolfgang Enard (Department Biology II, Ludwig-Maximilians University Munich, Germany).

**Table S 2 Significant gene set enrichment (category "biological process", Fisher's exact test: <0.01) based on differentially regulated genes by Miuraenamide A compared to jasplakinolid**  
The GOs (gene ontologies) marked in grey are unique for the comparison Miuraenamide A vs. jasplakinolide and do not show up in Miuraenamide A or jasplakinolide vs. control (provided by Prof. Dr. Wolfgang Enard, Department Biology II, Ludwig-Maximilians University Munich, Germany).

**Table S 6 List of genes significantly regulated in HUVECs by treatment with ChivoA**

62 genes were downregulated and 39 genes were upregulated after treatment with chivosazole A (20 nM ChivoA for 4h). Orange: down regulated genes, green: upregulated genes. (provided by Prof. Dr. Wolfgang Enard, Department Biology II, Ludwig-Maximilians University Munich, Germany).

**Table S 8 List of genes significantly regulated in HUVECs only by ChivoA or only by LatB**

29 genes were only downregulated by chivosazole A, but not by latrunculin B, and 19 were only upregulated by chivosazole A and not by latrunculin B. 5 genes were specifically downregulated and 40 upregulated by latrunculin B in contrast to chivosazole A. Orange: down regulated genes, green: upregulated genes (provided by Prof. Dr. Wolfgang Enard, Department Biology II, Ludwig-Maximilians University Munich, Germany).

DMEM	Dulbecco's Modified Eagle Medium
DMSO	Dimethyl sulfoxide
DNA	Deoxyribonucleic acid
DTT	Dithiothreitol
ECGM	Endothelial cell growth medium
EDC	1-ethyl-3-(3-dimethylaminopropyl)- carbodiimide
EDTA	Ethylenediaminetetraacetic acid
EGTA	Ethylene glycol-bis(2-aminoethylether)-N,N,N',N'-tetraacetic acid
EM	Electron microscopy
EMT	Epithelial-to-mesenchymal transition

---

et al.	And others
FCS (1)	Fetal calf serum
FCS (2)	Fluorescence correlation spectroscopy
Fig.	Figure
FMI	Forward migration index
g	Gram
GOs	Gene ontologies
h	Hour
HUVECs	Human umbilical vein endothelial cells
IC 50	Half maximal inhibitory concentration
i.e.	<i>Id est</i> (that is)
Jaspla	Jasplakinolide
kcal/mol	Kilocalorie per mole
kDa	Kilodalton
L	Liter
LatB	Latrunculin B
M	Molar
MD	Molecular dynamics
MES	2-(N-morpholino)-ethanesulfonic acid
MET	Mesenchymal-to-epithelial transition
mg, ml, mM, mm	Milligram, milliliter, millimolar, millimetre
min	Minute
MiuA	Miuraenamide A
MRTF	Myocardin related transcription factor
nM, nm	Nanomolar, Nanometre
PBS	Phosphate Buffered Saline
Pen / Strep	Penicillin/Streptomycin
PFA	Paraformaldehyde
pH	Potential of hydrogen

---

RMSD	Root mean square deviations
rpm	Revolutions per minute
RT	Room temperature
s	Second
SATB1	special AT-rich sequence-binding protein 1
SEM	Standard error of the mean value
SDS	Sodium dodecyl sulfate
SDS-PAGE	Sodium dodecyl sulfate-polyacrylamide gel electrophoresis
T $\beta$ 4	Thymosin $\beta$ 4
TCE	2,2,2-Trichloroethanol
T/E	Trypsin/EDTA
TEMED	N, N, N', N' tetramethylethylene diamine
TIRF	Total internal reflection fluorescence
Tris	Trishydroxymethylaminomethane
V	Volt
v/v	Volume per volume
w/v	Weight per volume
$\mu$ g, $\mu$ l, $\mu$ M, $\mu$ m	Microgram, microliter, micromolar, micrometre
$^{\circ}$ C	Degree Celsius

---

## 8.5 Publications

Karine Pozo, Stefan Zahler, Keisuke Ishimatsu, Angela M. Carter, Rahul Telange, Chunfeng Tan, **Shuaijun Wang**, Roswitha Pfragner, Junya Fujimoto, Elizabeth Gardner Grubbs, Masaya Takahashi, Sarah C. Oltmann and James A. Bibb

*Preclinical characterization of tyrosine kinase inhibitor-based targeted therapies for neuroendocrine thyroid cancer*

Oncotarget. 2018; 9:37662-37675.

**Shuaijun Wang**, Florian Gegenfurtner, Alvaro H. Crevenna, Christoph Ziegenhain, Zane Kliesmete, Wolfgang Enard, Rolf Müller, Angelika M. Vollmar, Sabine Schneider and Stefan Zahler

*Chivosazole A modulates protein-protein-interactions of actin*

Journal of Natural Products. 2019 Jul 1.

**Shuaijun Wang**, Alvaro H. Crevenna, Ilke Ugur, Antoine Marion, Iris Antes, Uli Kazmaier, Maria Hoyer, Don C. Lamb, Florian Gegenfurtner, Zane Kliesmete, Christoph Ziegenhain, Wolfgang Enard, Angelika Vollmar and Stefan Zahler

*Actin stabilizing compounds show specific biological effects due to their binding mode*

Scientific Reports. 2019.

## 8.6 Presentations

### 8.6.1 Oral presentations

**Shuaijun Wang**, Uli Kazmaier, Rolf Müller, Angelika Vollmar, Stefan Zahler

*Chivosazole A, a novel actin-binding macrolide from myxobacterium, modulates protein-protein-interactions*

Graduate School Life Science Munich (LSM) retreat 2019

30<sup>th</sup> April – 3<sup>rd</sup> May, June, 2019, Munich, Germany

### 8.6.2 Poster presentations

**Shuaijun Wang**, Uli Kazmaier, Rolf Müller, Angelika Vollmar, Stefan Zahler

*Biological activities of actin binding compounds in endothelial cells*

EMBO | EMBL Symposium: Actin in Action: from Molecules to Cellular Functions

7<sup>th</sup> -10<sup>th</sup>, September, 2016, Heidelberg, Germany

**Shuaijun Wang**, Uli Kazmaier, Rolf Müller, Angelika Vollmar, Stefan Zahler

*Biological activities of actin binding compound Miuraenamides A in endothelial cells*

Graduate School Life Science Munich (LSM) retreat 2018

25<sup>th</sup> - 28<sup>th</sup>, June, 2018, Munich, Germany

## 8.7 Curriculum vitae

### Personal data

**Name** Shuaijun Wang  
Date of birth 06.08.1989  
Place of birth Changchun, Jilin Province, P.R. China  
Nationality Chinese

### Contact

Pharmaceutical Biology  
Department of Pharmacy - Center for Drug Research  
Ludwig-Maximilians-University Munich  
Butenandtstr. 5-13, Haus B  
81377 Munich Germany  
E-mail : [crystaljadav@gmail.com](mailto:crystaljadav@gmail.com)

### Education

09.2015 - now PhD study in Pharmaceutical Biology,  
Department of Pharmacy,  
Ludwig-Maximilians-University Munich, Germany  
Prof. Dr. Stefan Zahler  
09.2012 - 06.2015 Master study in Pharmacology,  
Department of Pharmacology,  
School of Pharmaceutical Sciences,  
Jilin University, P.R. China,  
Prof. Dr. Dayuan Sui  
09.2004 - 06.2008 Bachelor study in Pharmaceutical Sciences,  
School of Pharmaceutical Sciences,  
Jilin University, P.R. China,

### Grants/Funding

Since 09.2015 financial support by China Scholarship Council  
Since 01.2018 Life Science Munich doctoral programme

## 8.8 Acknowledgements

Firstly, I would like to express my sincere gratitude to my supervisor Prof. Dr. Stefan Zahler for giving me the chance to come to Germany and join this big research team. Thank for his continuous support of my Ph.D study and related research work, for his patience, motivation, and immense knowledge. His immense knowledge, motivation and patience have supported me a lot in the research writing. Conducting the academic study regarding such a difficult topic couldn't be as simple as he made this for me. He is my mentor and a best advisor for my doctorate study beyond the imagination.

Secondly, I would like to thanks to Prof. Dr. Angelika Vollmar for giving me the opportunity to perform my PhD studies in her laboratories. Many thanks for her always giving the encouragement and sharing insightful suggestions on my research work during each achievement meeting and progress report. It was a true pleasure and honor for me to be part of AK. Vollmar research group. Thank her as well for offering her time and interest to be in my examining committee.

Moreover, I am very grateful to Dr. Alvaro H. Crevenna, thank for his patience and effort teaching me TIRF assay. Thank for his support and help in all my scientific questions as well as his contribution to my research work.

Thanks to the Graduate School Life Science Munich for offering an international doctoral program for me. And thank as well to Prof. Dr. Christian Grimm for being my TAC meeting member in LSM program.

I want to sincerely acknowledge the time and interest of the members of my examining committee: Prof. Dr. Ernst Wagner, Dr. Stylianos Michalakis, Dr. Oliver Thorn-Seshold and Prof. Dr. Christian Grimm.

I would like to thank to the expert technical assistance by Jana Peliskova. I would always remember her effort and patience on me when teaching me technical skills in spite of our language barriers.

Very special thanks to the cooperation partners, who has contributed to this work: Thanks to Dr. Alvaro H. Crevenna (Biomolecular Self-Organization Laboratory, ITQB-Universidade Nova de Lisboa) for analyzing TIRF assay parameters, Dr. Sabine Schneider (Department of Chemistry, TUM, Germany), Prof. Dr. Don C. Lamb Department Chemistry, LMU, Germany), Prof. Dr. Wolfgang Enard (Department Biology II, LMU, Germany) and Prof. Dr.

---

Iris Antes (Protein Modelling group, TUM, Germany) for providing their extreme valuable experiment data to support my doctoral thesis.

I thank all people in Vollmar lab for creating such a great and lovely lab environment! Kerstin and Florian, thank them for being my seniors, always teaching and helping me with my research work. And Lisa, Themis, Daniel, thanks them all for being together with me in Prof. Zahler's group. Thanks to Lucas and Pengyu for being great friends and providing me emotional support in the last one year. I would also thank to all the other labmates for the last four years we spent together. Thanks to Gulia and Lushuang for doing their internship under my instruction. It enriched my knowledge and improved my mentoring ability. The whole four years of PhD experience really means a lot to me.

Thanks to the China scholarship Council and Chinese Government Graduate Student Overseas Study Program for offering me the opportunity to study abroad and for the financial support that allows me to stay in Germany.

Special thanks to my master supervisor, Prof. Dayuan Sui, who is always pushing me forward, both scientifically and personally.

I would like to thank my parents for their indescribable support from the other side of the world. Their love and trust have always motivated me so that I could only pay attention to the studies and achieve my objective without any obstacle on the way.

Last but not least, I would like to thank my friends, Fanfan Sun, Yanfen Li, Yu-Kai Chao for the great time we spent together in Munich.
