Mündliche Prüfung am: 05.12.2024

Acknowledgement

This dissertation has been quite a journey, on which many wonderful people accompanied me. To all of you, thank you very much for being a part of this.

First, I would like to thank Prof. Hendrik Zipse for offering me this opportunity by welcoming me into his group. He allowed me to shape my research project as I saw fit and still offered advice when needed.

Prof. Ruth Gschwind, I thank for being my “Zweitgutachter” and for joining in on countless (zoom) discussions about ion pairs, conductivity models, DOSY curves and more. She always brought a fresh perspective and a lot of enthusiasm to these discussions.

Also, I would like to extend my thanks to Dr. Armin Ofial. Also, for participating in the countless (zoom) discussions about ion pairs and their nucleophilicity measurements, and for offering his advice and expertise. He kindly allowed me to use his groups equipment for numerous measurements.

Maximilian Franta, I thank for his collaboration and the many hours he spent measuring DOSY NMRs for this project.

These four people will be fondly remembered by me as “ion pair team”. Without them a large part of this thesis would not have been possible.

I would also like to thank the analytical department of the Ludwig-Maximilians-Universität, Dr. Peter Mayer for determining crystal structures and all other employees who have supported me in my work.

Furthermore, I would like to thank my colleagues for the daily collaboration in the lab. Dr. Harish Jangra, Dr. Julian Helberg, Dr. Benjamin Pölloth, Dr. Stefanie Mayer, Dr. Salavat Ashirbaev and Dr. Fabian Zott welcomed me into the group and always offered help and advice when needed. Harish and Fabian always knew how to fix any computational issue, and with Benjamin and Steffi I often discussed the joy of organocatalysis. Also, I want to thank my current colleagues Caroline Carter, for our regular discussions about chemistry and life in general, Jan Brossette for his help with any computational questions I have had, Kuangjie Liu for his help on several occasions and Marc Krähling, who will continue the project of pyridinamide ion pairs. Additional thanks to Steffi, Caroline, and Marc for proofreading parts of this work.

Special thanks to my friends who helped me recharge when work got demanding. Game nights with Alex, Kathi, Tobi, and Stefan were always full of laughter and fun. Meet-ups with Carina and Kim always helped me find my balance again. Lunch dates with Kyra were always a welcome change on a workday.

Last, but not least I want to thank my loved ones who made my doctorate possible in the first place: my parents, my brother, my grandmothers and grandfathers, my aunts, uncles, and cousins. Thank you for your affection and your support. One of you gave me the most memorable push of all: “Why don't you just finish it so you can be done with it!” And sometimes that is all you need to hear.

The biggest thank you goes to Stefan who helped me through all the ups and downs during my dissertation in the last five years. He always encouraged and had an open ear for all my troubles. Thank you for being there for me.

Summary

This thesis was conducted as part of the research training group “Ion Pair Effects in Molecular Reactivity”. The RTG 2620 focuses on exploring the reactivity, structure, and mechanisms of ion pairs in chemical reactions, aiming to bridge the gap between experiment and theory. Within the framework of my thesis, this led to a comprehensive study of pyridinamide ion pairs in apolar solvents. As a result, a toolbox of various methods was used, allowing conclusions to be drawn about their association state and reactivity in apolar solvents.

Chapter 2: Highly Nucleophilic Pyridinamide Anions in Apolar Organic Solvents due to Asymmetric Ion Association¹

Pyridinamide phosphonium ion pairs were studied in dichloromethane using a combination of conductivity measurements, diffusion-ordered (DOSY) NMR, and kinetic measurements utilizing a refined ionic strength-controlled benzhydrylium ion methodology. This approach offered specific insights into the ion concentrations, their association state and nucleophilicity of the involved anion. It was revealed that pyridinamide tetraphenylphosphonium salts aggregate asymmetrically in dichloromethane solution, forming cationic and anionic sandwich-type complexes along with their corresponding counterion. The nucleophilicity

of free pyridinamide ions exceeds that of the neutral reference nucleophile 9-azajulolidine (TCAP) by up to two orders of magnitude. We propose that asymmetric association in organic solvents of low polarity might offer a pathway to enhance the reactivity of anionic nucleophiles.

Chapter 3: Pyridinamide Ion Pairs – Design Principles for Super-Nucleophiles in Apolar Organic Solvents²

The developed comprehensive analytical protocol, combining conductivity, diffusion-ordered NMR, and photometric kinetic measurements, was used to characterize a library of pyridinamide ion pairs in organic solvents of low polarity. The results indicate a strong influence of cation size on association patterns, with larger cations favoring cationic triple ion sandwich complexes, which leave the free and highly nucleophilic anions as reactive species.

Kinetic studies using the ionic strength-controlled benzhydrylium ion method demonstrate that pyridinamide anions exhibit a significantly enhanced nucleophilicity compared to established organocatalysts, particularly in low polarity solvents. With the gained insights the design of next generation pyridinamide ion pairs can be optimized to modulate the catalytic activity by controlling the asymmetric association. The Brønsted basicity of pyridinamide salts was quantified via the determination of their pK_a values in water and water/organic solvent mixtures and their Lewis basicity was quantified through quantum chemically calculated cation affinity data. Furthermore, the catalytic activity of pyridinamide ion pairs was tested in the reaction of isocyanates with alcohols.

Chapter 4: Application of Ion Pair Catalysts in Acylation Reactions

Pyridinamide ion pairs represent a promising class of organocatalysts that have demonstrated their catalytic potential in addition reactions such as the urethane synthesis and the *aza*-Morita-Baylis Hillman

reaction. This study examined their catalytic activity in acylation reactions, using the acylation of 1-ethynylcyclohexanol as a benchmark reaction. The acylation with acetic anhydride was studied, with neutral organocatalysts dimethylamino pyridine (DMAP) and TCAP serving as references. The effective reaction rates k_{eff} ($M^{-1} s^{-1}$) showed that the most active pyridinamide ion pair catalyst exhibited about half the catalytic activity of TCAP. However, the previously most active pyridinamide ion pair catalyst only displayed moderate activity in this benchmark reaction. The observed deviation in catalytic activity led to an investigation of potential protonation-induced deactivation, which was ruled out by testing various auxiliary bases. To identify the cause of this moderate activity, further studies are required. Solvent effects were examined, showing that the choice of solvent significantly influences the catalytic activity of both pyridinamide catalysts and neutral organocatalysts, with the effect being more pronounced for pyridinamide salts. In a second benchmark reaction, four selected pyridinamide ion pair catalysts were employed in the acylation of 1-ethynylcyclohexanol with benzoic anhydride. The observed effective reaction rates k_{eff} ($M^{-1} s^{-1}$) were lower than those observed in the benchmark reaction with acetic anhydride. Nevertheless, the gap in catalytic efficiency between TCAP and the most active pyridinamide ion pair catalyst was reduced by half in these reaction conditions. These findings suggest that pyridinamide ion pairs could be effective in reactions that produce acidic byproducts. However, to fully optimize their catalytic potential in acylation reaction, further studies have to be conducted.

Chapter 5: Reactivity Enhancement of Chiral Lewis Catalysts through Ion Pair Formation

In the fifth chapter, we shift our focus to the synthesis of chiral pyridinamide derivatives. As already demonstrated, utilizing an anionic pyridine moiety can significantly increase the catalytic potential of the resulting organocatalyst. We intended to further

explore this approach by selecting a known neutral chiral organocatalyst with high selectivity but poor reactivity, using its scaffold as a reference for the synthesis of a chiral pyridinamide. Vedejs' chiral organocatalyst, DMAP with a chiral substituent at the C2 position, was chosen as reference for this study. The original synthesis began with DMAP and involved a protection step, followed by metalation at the C2-position with lithium tetramethylpiperidine (LiTMP) and subsequent acylation with pivaloyl chloride. This was followed by an enantioselective reduction using a borane complex, yielding a chiral alcohol, which was then methylated using potassium hydride and methyl iodide to form the desired catalyst. The goal of this study was to synthesize a chiral pyridinamide ion pair catalyst based on the scaffold of Vedejs' chiral DMAP catalyst. Multiple attempts were made using starting materials such as 4-aminopyridine and 2-bromopyridine derivatives. Despite obtaining promising intermediates, several challenges were encountered in isolating the desired product. Various synthetic modifications were explored, including lithium-bromide exchange and subsequent acylation or nitrile addition, though without success. Further studies are needed to establish a synthetic route. Additionally, quantum chemical calculations were conducted to assess the Lewis basicity and stereoinductive potential of future chiral pyridinamide salts.

General Comments and Conventions

As part of this thesis is already submitted or prepared for publication, my contributions to multi-author publications are explicitly mentioned at the beginning of every chapter. The contributions from other authors are omitted from the experimental part. The main project of my dissertation is partitioned into two parts: Chapter 2 focuses on the development of the methodology and Chapter 3 on the insight gained from applying said methodology. This leads to unavoidable changes in the numbering when moving from Chapter 2 to Chapter 3. The following substrates will be consecutively numbered throughout starting in Chapter 2: 4-dimehtylaminopyridine (DMAP, **1**), 9-azajulolidine (TCAP, **2**) and pyridinamide salts **3a** and **4a** (see Chart 0.1). In Chapter 3 additional pyridinamide salts will be numbered consecutively.

Chart 0.1. Structures of neutral organocatalysts DMAP (**1**) and TCAP (**2**), and pyridinamide ion pair catalysts **3a-d**, **4-6a**.

Since Chapter 2 only includes the pyridinamide ion pair **3a** and **4a**, consequently, the numbers of other reoccurring compounds will change when moving forward to Chapter 3, where more pyridinamide ion pairs will be discussed. To mitigate confusion, the concerned compounds with their respective number per chapter and any potential changes regarding the numbering in between chapters are listed below in Table 0.1.

Table 0.1. Compounds with their respective numbering in Chapter 2 and Chapter 3.

Compound	Numbering in Chapter 2	Numbering in Chapter 3
<p>(lil)₂CH⁺BF₄⁻</p>	5a	8a
<p>(jul)₂CH⁺BF₄⁻</p>	5b	8b
<p>(ind)₂CH⁺BF₄⁻</p>	5c	8c
PPh ₄ BF ₄	6	7a

Starting with Chapter 3 all compounds will be numbered consecutively.

Chapter 1. Introduction

1.1 Organocatalysis

Organocatalysis refers to the acceleration of chemical reactions using small organic molecules as catalysts. These molecules typically contain elements such as carbon, nitrogen, sulfur, or phosphorus.^[1] The term “organocatalysis” was first introduced by MacMillan in 2000, even though, the concept itself has been known since the 19th century, when Liebig catalyzed the reaction of cyanide and water to form oxamide by using acetaldehyde as the catalyst.^[2,3] Despite its early origins, systematic research about organocatalysis has only gained significant momentum over the past two decades, establishing it as a widely studied and impactful area in organic chemistry.^[3,4] As shown in Figure 1.1, organocatalysis can be classified based on the type of catalyst used for the transformation.

Figure 1.1. Classification for areas in organocatalysis based on the type of catalyst.

Broadly, organocatalysis can be partitioned into the two major branches covalent and non-covalent catalysis. While covalent catalysts form a bond with the substrate, non-covalent catalysts use non-covalent interactions (NCIs), such as hydrogen-bonding, ion binding, halogen bonding, and/or dispersion interactions to coordinate with the substrate.^[5] The classification of these catalysts often depends on the degree of the inherent directionality in the interaction between the catalyst and the substrate (see Figure 1.2).

For instance, covalent iminium-based catalysis^[6,7] relies heavily on strong, directional interactions, and has been proven highly effective for enantioselective carbonyl activations. Conversely, catalysts that interact through hydrogen-bond donors, such as organic-based Lewis acids and Brønsted acids^[8,9], show weaker and less directional interactions. Ion pairing interactions are even less inherently directional, but represent a powerful strategy for enantioselective transformations when charged intermediates are involved, even though finding the right catalyst design is challenging.^[10,11]

Figure 1.2. Trend of increasing inherent directionality in catalyst-substrate interactions for non-covalent asymmetric catalysis systems with B^*H = chiral hydrogen bond donor; A^- = anion; C^+ = cation, * = chiral ion).^[11]

In terms of covalent organocatalysts, four distinct categories can be defined based on their role within the catalytic cycle: Brønsted acid or base catalysis, where the catalyst donates or accepts a proton, and Lewis base or acid catalysis, where the catalyst donates or accepts electron pairs.^[12,13] This work focuses on nitrogen-based Lewis base catalysts, which are widely applied in various synthetic processes.

1.1.1 Lewis Base Catalysis

Denmark^[14] defined Lewis base catalysis as a “process by which an electron-pair donor increases the rate of a given chemical reaction by interacting with an acceptor atom in one of the reagents or substrates. The binding event may enhance either the electrophilic or nucleophilic character of the bound species.” Jensen^[14,15] proposed that all Lewis acid-base interactions could be classified in terms of the interacting orbitals. The most commonly recognized form of Lewis base catalysis is represented by $n\text{-}\pi^*$ interactions which occur between the nonbonding electron pair n of the Lewis base and the antibonding π^* acceptor orbital, which are contained in carbonyls, alkenes or other unsaturated functional groups. In the field of Lewis basic organocatalysts nitrogen-based catalysts are the most common ones, followed by phosphanes and sulfides. The use of nitrogen-based nucleophilic catalysts can be traced back to 1898, when Einhorn and Hollandt^[16] demonstrated that pyridine facilitated acylation reactions of alcohols and phenols. This discovery provided the foundation for further advancements in this field. The development of 4-dimethylaminopyridine (DMAP) by Litvinenko and Kirichenko^[17] in 1967, and independently by Steglich and Höfle^[18] in 1969, marked a significant milestone. DMAP has since been a widely used catalyst for accelerating group transfer reactions such as acylations,^[19–22] alkylations,^[23] and silylations.^[24,25] Since then, continuous efforts have been undertaken to develop more catalytically active Lewis base catalysts. Progress was made by introducing a better electron donating group such as pyrrolidine, yielding of 4-pyrrolidinopyridine (PPY)^[20,21] in 1970. A significant advance was achieved by conformational fixation of the dialkylamino group in DMAP, leading to the development of tricyclic 9-azajulodine (TCAP)^[26] in 2003. The increased catalytic potential is attributed to stronger $n\text{-}\pi^*$ interactions between the nitrogen lone pair and the acylated intermediate, further improved by the increased positive inductive effect of the alkyl substituent towards the pyridine ring. Therefore, TCAP surpasses DMAP by a factor of approx. six in catalytic benchmark reactions due to the enhanced stabilization of the cationic acylated pyridinium intermediate.

Building on the success of the TCAP moiety, researchers have explored various structural modifications to further improve the catalytic efficiency of DMAP-based organocatalysts as it can be seen in Chart 1.1. For example, guanidinyll substituents have been introduced as electron-donating group in pyridine-based catalysts of type **A**.^[27] Bicyclic and tricyclic systems of type **B** have been generated through the incorporation of multiple amin-donor groups.^[28,29] Other variation included the introduction of alkyl groups and additional nitrogen atoms into the ring system, resulting in catalysts such as 3,4-diaminopyridine of type **C** and 3,4,5-triaminopyridine derivatives (**D**).^[28,30] Based on computational studies using methyl and acetyl cation affinity values as predictive tools by the Zipse group,^[29] Lewis base catalysts of type **B** and **C** were expected to be more catalytically active than TCAP. However, this computational prediction was not confirmed experimentally.

Chart 1.1: Pyridine-based Lewis based catalysts.

Thus, while all these new catalysts are more reactive than DMAP, the catalytic activity of TCAP has not yet significantly surpassed. In 2020, the Namba group synthesized 1,1,7,7-tetramethyl-9-azajulolidine (TMAJ, **E**),^[31] a derivative of TCAP, which exhibited 1.5 times the catalytic activity of TCAP in a benchmark acylation reaction, which is in agreement with quantum chemical studies conducted by Zipse *et al.*^[32] Shortly thereafter, Dyker *et al.* introduced 4-iminophosphorano pyridines (**F**), a new class of neutral organocatalysts, in which the most reactive derivative outperformed TCAP by a factor of two in acylation reactions.^[33] As it can be seen in Chart 1.1, the pyridine ring has been systematically substituted with various types of donor substituents to generate a Lewis base organocatalyst with enhanced catalytic potential.

Recently, Helberg and Zipse^[34] introduced a long-overlooked approach to increase the electron density of the pyridine ring by using stabilized 4-pyridinylamide anions. The developed pyridinamide ion pair (**G**) proved to be more catalytically active than TCAP by a factor of three in urethane reactions and by a factor of 15 in an inherently slow *aza*-Morita-Baylis Hillman reaction. For the first time in years a Lewis base catalyst displayed a catalytic potential significantly higher than TCAP. In 2023, Kass *et al.*^[35] followed a similar approach by introducing 3-pyridinyl (**H_3**) and 4-pyridinyl (**H_4**) borate salts, which exhibit catalytic activity comparable to the most active pyridinamide ion pair catalyst in urethane reactions.

Though we will discuss *pyridinamide ion pair catalysts* in this thesis, based on their role in the catalytic cycle and their theorized type of connection with the substrate, they would be classified as Lewis base catalysts. Nevertheless, we wanted to give a short conceptual survey of what the field of *ion pair catalysis* entails.

1.1.2 Ion Pair Catalysis

Non-covalent organocatalysis has become a fundamental area of research in modern organic chemistry and can be divided into two key areas: hydrogen-bonding catalysis^[36,37] and ion pair catalysis.^[11,37,38] Hydrogen-bonding catalysis involves the activation of neutral electrophiles by neutral catalysts, whereas ion pair catalysis is characterized by the interaction of charged species. Since almost all organic reactions proceed via at least one charged intermediate, ion pair catalysis is a versatile tool for controlling both reactivity and selectivity. The concept of utilizing non-covalent interactions has been long established, especially in the field of phase-transfer catalysis (PTC), which emerged in the 1960s with the use of quaternary ammonium and phosphonium salts to mediate reactions between reagents in two immiscible phases.^[39–41] While PTC is a well-known form of non-covalent organocatalysis, ion pair catalysis has

emerged as a distinct area, focusing on interactions between charged species within the same phase, thus extending the scope of classical PTC.^[11,41] The design of catalysts that exploit non-covalent interactions, particularly ion pairing, presents unique opportunities for achieving selectivity in chemical transformations. As a result, ion pair catalysts have found widespread application in asymmetric catalysis.^[42]

In ion pair catalysis, two key approaches have been identified: ion-binding catalysis^[11,43] and counterion-directed catalysis^[44] (see Figure 1.3). These approaches are further subdivided into anionic and cationic strategies, based on the charge of the interacting species. Counterion-directed catalysis typically involves a chiral charged catalyst directing the reaction through ion-pair interactions, whereas ion-binding catalysis employs a neutral catalyst that binds non-covalently to a charged species, forming a supramolecular complex.

Figure 1.3. A) General activation mode of hydrogen-bonding catalysis. B) Types of asymmetric ion pairing catalysis.

Note that the concepts of ion-binding catalysis and counterion-directed catalysis differ significantly from one another. In counterion-directed catalysis, a charged (chiral) catalyst is used to direct the reaction via ion pairing interaction, whereas in ion-binding catalysis a neutral catalyst binds non-covalently to a charged species, resulting in a supramolecular complex. In recent year, ion pair catalysis has been further developed and novel approaches to design selective ion pair catalysts have been considered.^[45–47] With ongoing research, the concept of ion pairing is also combined with other types of catalysis such as photochemical^[48] or transition metal catalysis^[49] which opens the new pathways to highly stereoselective organic transformations.

Understanding the challenges of designing selective asymmetric ion pair catalysts requires an appreciation of the underlying physical principles of ion pairs. The concept of ion pairs as distinct chemical entities was introduced in 1926 by Bjerrum.^[50,51] An ion pair consists of two oppositely charged ions, a cation and an anion, that are associated with each other due to electrostatic interactions, but are not covalently bonded. The strength of an ionic interaction is dictated by Coulomb's law^[50,51] (eq. 1.1), in which the interaction energy E is a function of the distance between the two charges q_1 and q_2 , and is inversely related to the distance r between the ions and the relative permittivity ϵ of the surrounding medium.^[11,43] Anslyn and Dougherty^[52] further clarified that ion pairs form when the electrostatic attraction between ions exceeds the thermal energy required to separate them via Brownian motion. This interaction is described by the Bjerrum length λ_B , which defines the distance between the two charged species q_1 and q_2 , at which electrostatic forces dominate over thermal energy as described in eq. 1.2 with ϵ_r being the relative permittivity of the medium, ϵ_0 being the vacuum permittivity, k_B being the Boltzmann constant, and T being the absolute temperature. With eq. 1.2, the distance where electrostatic interactions matter in catalysis can be calculated. Therefore, solvation effects play an important role in ion pair catalysis.

$$E = \frac{q_1 q_2}{4\pi\epsilon\epsilon_0 r} \quad (1.1)$$

$$\lambda_B = \frac{q_1 q_2}{4\pi\epsilon\epsilon_0 r} \times \frac{1}{k_B T} \quad (1.2)$$

Ion pairs can be classified into three different types based on the degree of solvation as depicted in Figure 1.4.^[53,54] In solvents with lower permittivity, *contact ion pairs* with a common solvation shell and no solvent molecules between the anion and cation, are energetically favored, whereas *solvent-shared ions*, where the ions are separated by a shared solvation shell, and *solvent-separated ion pairs*, where each ion has its own solvation shell, are predominant in solvents with higher permittivity.^[53,55,56]

Figure 1.4. Types of ion pairs based on the degree of solvation and potentially higher aggregates.^[53]

In solvents of low permittivity, ion association can proceed beyond ion pairing to form triple ions or higher aggregates.^[53,54] The formation of triple ions, in this work also referred to as sandwich ions (Chapter 2 and 3), was first introduced by Fuoss and Kraus.^[57] The concept has been adopted by other researchers who studied the conductivity of electrolytes in non-aqueous solutions. Nevertheless, the evidence for triple ions formed through purely electrostatic forces is ambiguous. However, several theoretical arguments are favorable, as are our findings, which are discussed in Chapter 2 and 3 of this work.^[54]

1.2 Aim of this thesis

This introductory chapter provides an overview of the steps taken in the development pyridine-based Lewis base organocatalysts with enhanced catalytic activity. The most recent advancement was achieved by utilizing pyridinamide anions in combination with cations carrying aromatic substituents in organic transformation reactions. The initially conducted studies already demonstrated their enhanced catalytic potential in addition reactions such as the urethane synthesis and the *aza*-Morita-Baylis Hillman reaction.^[34] However, working with ionic substrates requires a new methodical approach and a distinct toolbox of techniques than those previously employed in our studies of neutral Lewis base catalysts.^[58,59] Classical methods such as ¹H-NMR spectroscopy, gas chromatography (GC) or high-performance liquid chromatography (HPLC) are insufficient for gaining the desired insights into the unique behavior of pyridinamide ion pairs in solution.

The primary objective of this study is to identify the association pattern of pyridinamide salts in organic solvents of low polarity and how the association state influences their reactivity. To achieve this goal, a combination of conductivity, diffusion-ordered NMR and photometric kinetic measurements is employed. Conductivity data and DOSY NMR combined are utilized to assess the association pattern. Association constants are determined based on the conductivity data alone, utilizing numerical simulations. Kinetic measurements utilizing a refined ionic strength-controlled benzhydrylium ion methodology quantify the reactivity of pyridinamide salts in terms of the nucleophilicity of the involved anion. By studying a library of pyridinamide salts according to this methodology, we seek to identify key

properties that will allow us to design the reactivity of future pyridinamide catalysts. Furthermore, we aim to investigate the scope of reaction types suitable for utilizing ionic pyridinamide catalysts. Finally, the synthesis of chiral pyridinamide anions is attempted.

Chapter 2. Highly Nucleophilic Pyridinamide Anions in Apolar Organic Solvents due to Asymmetric Ion Pair Association

Veronika Burger, Maximilian Franta, Armin R. Ofial*, Ruth M. Gschwind* and Hendrik Zipse*

J. Am. Chem. Soc., **2024**, *accepted* (DOI: 10.1021/jacs.4c14825).

Author contributions: Veronika Burger (V.B.) and Hendrik Zipse (H.Z.) conceived the study. All experimental studies were performed by V.B. with exception of DOSY NMR measurements, which were performed by Maximilian Franta (M.F.). The manuscript was jointly written by V.B., Ruth M. Gschwind (R.M.G.), Armin R. Ofial (A.R.O.) and H.Z. The supporting information was prepared by V.B. and M.F.

Additional information: The here displayed supporting information is an altered and shorted version of the submitted SI. The DOSY results are used for the explanation of findings, but no technical details are discussed in this thesis. These can be found in the original file. For comparison of this thesis and the original SI file, the numbering includes the original item number as shown below.

Highly Nucleophilic Pyridinamide Anions in Apolar Organic Solvents due to Asymmetric Ion Pair Association

KEYWORDS: conductivity, DOSY, asymmetric association, nucleophilicity, kinetics.

ABSTRACT: Free ions in organic solvents of low polarity would be valuable tools for the activation of low reactivity substrates. However, the formation of unreactive ion pairs at concentrations relevant for synthesis has prevented the success of this concept so far. On the example of highly nucleophilic pyridinamide phosphonium salts in dichloromethane we show that asymmetric aggregation offers a solution to this general problem. A combination of conductivity, diffusion-ordered NMR (DOSY), and kinetic measurements utilizing a refined ionic strength-controlled benzhydrylium ion methodology enables unique insight about the number of ions with their aggregation/association state and nucleophilicity of the involved anions. This approach reveals that pyridinamide tetraphenylphosphonium salts aggregate in dichloromethane solution asymmetrically to sandwich-type cations and anions together with their free counterions. The nucleophilicity of free pyridinamide ions exceeds that of the neutral reference nucleophile 9-azajulolidine (TCAP) by up to two orders of magnitude. Based on these results we suggest that asymmetric aggregation in organic solvents of low polarity might be a general pathway to boost the reactivity of anionic nucleophiles.

INTRODUCTION

Lewis basic pyridines, such as 4-(dimethylamino)pyridine (DMAP, **1**)^[1] or the more reactive 9-azajulolidine (TCAP, **2**)^[2] are frequently used catalysts for group transfer reactions such as acylations,^[3-6] esterifications,^[4,6] alkylations,^[7] and silylations (Chart 1).^[8,9] The nucleophilicity of these catalysts, together with other donor-substituted pyridines, has been quantified using Mayr's benzhydrylium ion method.^[10-13] Even higher nucleophilicities and possibly also higher catalytic activities in Lewis base-mediated reactions may be expected for anionic Lewis bases. Given that anionic reagents unavoidably require a counter-cation, such salts tend to form ion pairs when dissolved in organic solvents of low polarity, such as dichloromethane.^[14,15] This ion clustering has beneficially been used in ion pair catalysis,^[16-18] which extends from classical cationic phase-transfer (PT) catalysis^[19] to applications in asymmetric synthesis.^[16,20-22] Recently, the Zipse group introduced Lewis basic pyridinamide ion pair catalysts, which outperformed TCAP and other neutral organocatalysts in selected catalytic benchmark reactions.^[23,24]

Chart 1. Structures of neutral organocatalysts DMAP (1**) and TCAP (**2**), and of pyridinamide ion pair catalyst **3a** and **4a**.**

The pyridinamide phosphonium salts (such as **3a** and **4a** in Chart 1) investigated so far show the general usefulness of the

concept of anionic nucleophilic organocatalysis, whose development tails that of neutral systems.^[25-27]

In order to minimize ion pairing effects, most kinetic studies aiming at the quantification of the reactivity of anionic nucleophiles have been performed in highly polar solvents (water, DMSO, etc.), often in combination with crown ether additives to further reduce the interactions between metal counter-ions and the reacting anion.^[28] In solvents of low polarity, the intrinsic nucleophilicity of a free anion should be far higher than in more polar media. However, the reactivity of anions is attenuated by ion pair formation, which also gives rise to non-linear effects and, thus, complicates systematic kinetic studies in organic solvents of low polarity (dichloromethane (DCM), THF, toluene etc.) commonly employed in organocatalysis.

In order to elucidate the underlying principles responsible for the experimentally observed high nucleophilicity of the anions in salts such as **3a** and **4a**, we report here a combination of conductivity measurements, diffusion-ordered NMR (DOSY) measurements at very low concentrations, and photometric kinetic measurements by utilizing an ionic strength-controlled benzhydrylium methodology. This combination of physico-chemical methods is expected to be generally applicable to ion pair chemistry and catalysis and may help to uncover the full potential of this field.

RESULTS AND DISCUSSION

Conductivity. Conductivity measurements have frequently been employed to quantify ion pairing effects.^[29-32] This method was therefore applied to determine the association of the cationic and anionic components of phosphonium salt **3a** selected here as a reference system in DCM and acetonitrile (MeCN). In both solvents **3a** is expected to be more reactive towards electrophiles than DMAP (**1**). Conductivity measurements were

performed for concentrations ranging from 0.02 mM to 1.0 mM as this appears to represent the onset of ion pair formation from free ions. At low electrolyte concentrations and for the case of non-interacting ions the experimentally determined conductivity κ depends on the specific molar conductivity Λ_m and the ion concentration $[A]$ as expressed in Equation (1).

$$\kappa = \Lambda_m[A] \quad (1)$$

In the polar aprotic solvent MeCN the ions of **3a** are well stabilized and exist mainly as free ions as indicated by a nearly perfect linear increase of conductivity with $[3a]$ (see SI, Figure S1). In the less polar solvent DCM the situation is more complex and two different domains can be seen in Figure 1B: (a) At low **3a** concentrations (region I, blue background, $[3a] < 0.04$ mM) the conductivity κ correlates linearly with $[3a]$, and (b) a non-linear part II at higher concentrations of **3a** (see Figure 1B beige background). While linear region I is assumed to represent the behavior of free anions (**3**) and cations (**a**), three ion association models were tested for non-linear region II. The first corresponds to the formation of ion pair **3a** (purple box in Figure 1A), while the second model involves formation of "sandwich cation" **a3a** together with free anion **3** (grey box in Figure 1A), and the third model considers formation of an analogous sandwich anion **3a3** (blue box in Figure 1A). The latter model was originally proposed to account for the properties of tetraalkyl ammonium salts in apolar solution,^[33] and subsequently employed for a variety of systems in organic solvents.^[34-37] In order to compare both models on equal footing, the respective equilibrium constants K_{IP} and K_{CAC} are defined relative to two equivalents each of free cation **a** and free anion **3**.

The 1:1 ion pair model retains the specific molar conductivity Λ_m derived from the linear region I and adds the effects of reducing the number of conducting species through formation of overall neutral (and thus inactive) ion pairs **3a**. Fitting this model to the observed conductivities up to an overall concentration of 1.0 mM yields ion pair formation constant $K_{IP} = 6.86 \times 10^5 \text{ M}^{-2}$ with good accuracy. The second model involves formation of sandwich cation **a3a** together with one equivalent of free anion **3** (grey box in Figure 1A), again combined with the specific molar conductivity Λ_m value obtained from linear region I. This model fits the observed conductivity values in the region up to 1.0 mM with sandwich association constant $K_{CAC} = 6.38 \times 10^6 \text{ M}^{-2}$ with equally good accuracy. This is also true for the third model involving formation of sandwich anion **3a3** (blue box in Figure 1A), for which the optimized association constant is $K_{ACA} = 6.38 \times 10^6 \text{ M}^{-2}$, numerically identical with K_{CAC} . The measured conductivity values together with the model predictions are depicted in Figure 1B (grey line for the **a3a** sandwich model, blue line for the **3a3** sandwich model, and purple dotted line for the 1:1 ion pair), which illustrates that all models fit the experimental conductivity curve equally well as indicated by largely similar RMSE values of $\text{RMSE}(K_{CAC}) = 0.17$, $\text{RMSE}(K_{ACA}) = 0.17$, and $\text{RMSE}(K_{IP}) = 0.30$, respectively.

DOSY NMR. Since conductivity measurements alone cannot provide direct information on the size of the contributing ions, DOSY-NMR measurements of **3a** were performed in DCM- d_2 for concentrations ranging from 0.005 mM to 1.0 mM (see Figure 1C and SI, Chapter 4 for detailed information). To enable DOSY measurements at these low concentrations, a 600 MHz spectrometer with a helium cryo probe and measurement times up to 16 h per sample were employed. The DOSY results were compared to calculated volumes of anion **3** (215 Å³), cation **a** (362 Å³), and contact ion pair **3a** (570 Å³), which are based on the van der Waals cavities employed in the

SMD continuum solvation model at the SMD(DCM)/B3LYP-D3/6-31+G(d) level of theory and indicated through the horizontal dashed lines in Figure 1C. At $[3a] = 0.005$ mM as the lowest concentration accessible for DOSY measurements we determined volumes of 367 Å³ for cation **a** and 192 Å³ for anion **3**, both of which agree closely with the SMD-derived volumes for cation **a** and anion **3**. At any concentration of **3a** > 0.005 mM considerably larger cation and anion volumes were observed already in region I (for full data see SI, Chapter 4). In the 1:1 association model shown in the purple box in Figure 1A, the volumes of both species are expected to converge to the SMD-derived value of 570 Å³ for the 1:1 ion pair **3a**. Instead, we persistently detected substantially different effective volumes for cation **a** and anion **3** also at higher concentrations (region II), and also note that the DOSY-derived volume for cation **a** exceeds that calculated for the 1:1 ion pair **3a**.

Figure 1. (A) 1:1 ion pair **3a**, sandwich cation **a3a**, and sandwich anion **3a3** as potential association models for anion **3** and cation **a** together with SMD-derived molecular volumes; (B) conductivity profile for **3a** in DCM fits to the calculated conductivity data for the 1:1 association model (purple dotted/dashed line), and the two sandwich association models (grey and blue line); (C) DOSY-derived ion volumes [Å³] compared to SMD-derived volumes (dashed horizontal lines) for single anion **3**, single cation **a**, ion pair **3a**, cation sandwich **a3a**, and anion sandwich **3a3**.

This latter observation can be rationalized with the sandwich ion models, where the DOSY-derived cation volume is expected to approach that of the **a3a** sandwich cation of 925 Å³. Combining the SMD-derived molecular volumes of ions with the equilibrium constants obtained from conductivity measurements allows us to predict concentration-dependent effective cation and anion volumes. These are shown in Figure 1C as a green line for anion and an orange line for cation volumes. Comparing experimentally derived with theoretically predicted volumes shows these to coincide quite well between 0.4 mM and 1.0 mM for the cation sandwich model.^[38] In contrast, the 1:1 model predicts volumes for both ions which are significantly lower than the experimental values (by more than 200 Å³ for the cation and >100 Å³ for the anion, see SI). This is also true for the **3a3** anion sandwich model that predicts larger anion than cation volumes not consistent with the DOSY experiments. The agreement between experimentally determined DOSY volumes and model predictions can be further improved by combining the two sandwich models considered here. This requires optimization of the two scaling factors α and β shown in Figure 1A such that the agreement with the conductivity data and the DOSY volumes is optimized. Best agreement for ion pair **3a** is found for $\alpha = 0.44$ and $\beta = 0.21$, which implies that 50% of the anion **3** is free while the other 50% is stored in the two sandwich complexes at $I = 1.0$ mM. In contrast, for ion pair **4a** the DOSY experiments show inverted relative ion volumes with larger values for anion **4** (see SI, Chapter 4). This is reflected by the mixing coefficients for ion pair **4a** amounting to $\alpha = 0.12$ and $\beta = 0.61$. This implies that 34% of anion **4** is free and 66% is hidden in the two sandwich complexes. The performance of these "mixed sandwich" models is quite satisfactory in concentration region II, but less so in region I with its rapid increase of ion volumes with salt concentration. It is an intriguing aspect of the formation of sandwich cation **a3a** that it generates one equivalent of free anion **3** as the counterion. The concentration of free anion **3** will quite obviously impact the efficiency of pyridinamide-anion based catalytic systems, where free anion **3** is expected to account for most of the observed activity.

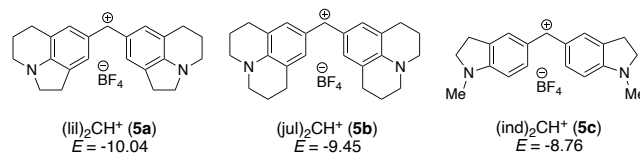

Kinetics. To characterize the nucleophilic reactivity of ion pairs **3a** and **4a** in an organic solvent of low polarity, such as DCM, we refined Mayr's well-known benzhydrylium ion method by implementing an ionic strength-control. This enabled the characterization of free anionic nucleophiles for the first time in DCM. Mayr's methodology has repeatedly demonstrated its utility to describe the reactivity of a wide range of carbon-, nitrogen, oxygen-, sulfur-, and phosphor-based nucleophiles in different solvents,^[39] including DMAP (**1**) and TCAP (**2**).^[10,11,39] In short, the benzhydrylium ion method involves the photometric monitoring of the reactions of colored benzhydrylium salts, such as **5a–5c** (Table 1) whose electrophilic reactivities are characterized by the solvent-independent parameters E , with nucleophiles used in excess concentration to achieve kinetics under pseudo-first order conditions. The first-order rate constants k_{obs} (s⁻¹) can then be obtained by fitting a mono-exponential decay function to the decreasing absorption of **5** during the reaction with **3**. The conductivity measurements (see SI, Figure S1) had shown that **3a** and **4a** fully dissociate into anions and cations when dissolved in MeCN. Accordingly, a linear increase of pseudo-first order rate constants k_{obs} with nucleophile concentrations **[3]** (or **[3a]**) was observed in the kinetics of reactions of **3a** with **5** [Equation (2)].

$$k_{\text{obs}} = k_2[\mathbf{3}] \quad (2)$$

$$\log k_2 = s_N(N + E) \quad (3)$$

Equation (2) thus yields the second-order rate constants k_2 (M⁻¹ s⁻¹) for the reactions of **3** with **5a–5c** in acetonitrile (Table 1). The rate constants k_2 for **3** are approx. three times larger than those for analogous reactions of **5** with DMAP (**1**) and quite similar to those for reactions with TCAP (**2**). Analyzing the kinetic data with the Mayr-Patz Equation (3) yields the nucleophilicity $N = 16.38$ ($s_N = 0.60$) of **3** in MeCN. Following exactly the same approach for ion pair **4a** yields $N(\mathbf{4a}) = 17.28$ ($s_N = 0.65$), in excellent agreement with the results obtained for these two systems in selected catalytic transformations.^[23]

Table 1. Second-order rate constants k_2 for the reactions of DMAP (1**), TCAP (**2**), and pyridinamide salts **3a** and **4a** with reference electrophiles **5a**, **5b**, and **5c** in MeCN (at 20 °C) analyzed by equation (3) to give the nucleophile-specific reactivity parameters N (and s_N).**

				
Cat	k_2 [M ⁻¹ s ⁻¹]			N (s_N)
	5a	5b	5c	
1 ^[a]	2.11×10^3	5.30×10^3	1.29×10^4	15.51 (0.62) ^[e]
2 ^[b]	6.30×10^3	—	4.17×10^4	15.60 (0.68) ^[e]
3 ^[c]	7.16×10^3	1.53×10^4	4.13×10^4	16.38 (0.60)
4 ^[d]	5.11×10^4	1.36×10^5	3.47×10^5	17.28 (0.65)

[a] Second-order rate constants k_2 from ref. [10]. [b] Second-order rate constants k_2 from ref. [11]. [c] Assuming that **[3]** = **[3a]**₀. [d] Assuming that **[4]** = **[4a]**₀. [e] Additional k_2 values from refs. [10,11] were used to determine N (and s_N).

The kinetics of reactions of **3a** with the reference electrophiles **5** in DCM solution, however, showed a more complex dependence of k_{obs} on **[3a]** in the concentration range from 0.01 to 1.0 mM (red and blue diamonds in Figure 2). In analogy to the conductivity measurements, an initial region I with linear k_{obs} vs. **[3a]**₀ relation was observed (Figure 2, blue background, experimental values marked in red). At higher **[3a]** values this is followed by non-linear region II (blue diamonds on beige background in Figure 2), where the observed rate constants deviate negatively from the linear correlation extrapolated from region I. The degree of deviation reflects the fraction of anion **3** captured in the (presumably) unreactive sandwich cation **a3a** and the (presumably) less reactive sandwich anion **3a3**.

Analysis of the kinetic data in region I (0.01 – 0.03 mM) is straightforward as conductivity measurements in combination with the sandwich association models indicate almost complete (> 97%) dissociation into separate ions **3** and **a**, that is **[3]** = **[3a]**₀. Application of eq. (2) then yields $k_2(\mathbf{5a}) = 1.84 \times 10^6$ M⁻¹ s⁻¹ as indicated by the dashed line in Figure 2.

In synthetic applications, the concentration of ion pair catalysts is usually 1.0 mM or higher, which is far into the non-linear region II. Increasing ion concentrations may impact the reaction rates not only through shifting the association equilibrium towards a higher fraction of ionic aggregates, but also through non-specific polarity effects. To assess the influence of the high salt concentration on the solvent polarity, we determined Reichardt's $E_T(30)$ values in DCM solutions with increasing concentrations of pyridinamide salt **3a** and additive $\text{Ph}_4\text{P}^+\text{BF}_4^-$ (**6**). As shown in Figure 2 this additive combines the common unreactive ions in the reaction mixture, that is, the BF_4^- of the benzhydrylium salts and the unreactive Ph_4P^+ counterion of the pyridinamide salts. We observed insignificant

changes of the $E_T(30)$ values even at total salt concentrations of up to 6.0 mM (see SI).

Figure 2. (A) Benzhydrylium ion reaction applied for the quantification of nucleophilicity of **3**. (B) Correlation of k_{obs} for the reaction of **5a** with **3a** for salt concentrations [3a] from 0.01 – 1.0 mM in DCM at 20°C (blue diamonds), and in the presence of additive PPh₄BF₄ (**6**) (turquoise dots).

We conclude, therefore, that addition of **6** to a reaction mixture of **3a** and **5a-c** does not change the overall polarity of the solvent system and only affects the position of the ion pairing equilibrium shown in Figure 2, where higher concentrations of Ph₄P⁺ (= **a**) give rise to an increase of [**a3a**]. To further investigate the effect of the Ph₄P⁺BF₄⁻ (**6**) additive, the ion volumes of selected **3a** + **6** mixtures were determined by DOSY measurements. The DOSY experiments show that the volumes of the cation and anion determined for **3a** + **6** mixtures at an ionic strength of $I = 1.0$ mM are in the same region as the volumes obtained for a pure **3a** solution at [3a] = 1.0 mM (for details see SI).^[40] The kinetics of the reaction of **3a** + **5a** was subsequently studied at constant ionic strength (I) of $I = 1.0$ mM as this represents the highest concentration of **3a** in this study. At [3a] < 1.0 mM, the ionic strength of the DCM solution was adjusted by addition of **6** such that in each kinetic measurement the condition [3a] + [6] + [5a] = 1.0 mM is fulfilled. By maintaining $I = 1.0$ mM, the rate constants k_{obs} for **3a** + **5a** reactions in DCM correlated linearly with [3a] in the entire concentration range from 0.01 to 1.0 mM (turquoise points in Figure 2). When we account for the fact that variable fractions of anion **3** are caught in unreactive sandwich cation **a3a** (and to a smaller extent also in anion sandwich **3a3**), and also consider the effect of additive **6** on [Ph₄P⁺], we obtain $k_2(\text{5a}) = 5.42 \times 10^5 \text{ M}^{-1} \text{ s}^{-1}$ for the reaction of **3** with **5a**, which is by a factor of 3.5 lower than k_2 obtained in the low-concentration region (Table 2). Analogous kinetic measurements at $I = 1.0$ mM were performed for reactions

of **3a** with the more reactive benzhydryl salts **5b** and **5c** (Table 2).

Table 2. Second-order rate constants k_2 of the reactions of DMAP (**1**), TCAP (**2**), and pyridinamide salt **3a** with the reference electrophiles **5a**, **5b**, and **5c** in DCM (at 20 °C).

Cat	$k_2 [\text{M}^{-1} \text{ s}^{-1}]$		
	5a	5b	5c
1 ^[a]	6.45×10^3	9.84×10^3	4.96×10^4
2 ^[b]	1.42×10^4	3.11×10^4	1.28×10^5
3 ^[c]	1.82×10^6 (LC)	4.23×10^6 (LC)	1.98×10^7 (LC)
3 ^[d]	5.42×10^5 (mix)	1.25×10^6 (mix)	4.64×10^6 (mix)
4 ^[e]	1.69×10^6 (mix)	4.19×10^6 (mix)	1.15×10^7 (mix)

[a] Second-order rate constants k_2 from ref. [10a]. [b] This work, see Supporting Information for details of the kinetic experiments. [c] Determined at [3] < 0.03 mM, that is, in the low concentration (LC) region I (Figure 2), by assuming [3] = [3a]₀. [d] Determined over a concentration range [3a] = 0.1 to 0.3 mM at constant ionic strength $I = 1.0$ mM (kept by addition of salt **6**) by assuming a mixed sandwich association model (see SI for details). [e] Determined over a concentration range [4a] = 0.04 to 0.1 mM at constant ionic strength $I = 1.0$ mM (kept by addition of salt **6**) by assuming a mixed sandwich association model

In DCM as the solvent, we note a moderate increase in the bimolecular rate constants k_2 when going from DMAP (**1**) to TCAP (**2**), but a significantly larger increase of the k_2 values for **3a** (Table 2). The k_2 values for reaction of **3a** with **5a-5c** in DCM in the low concentration (LC) region I (as defined in Figure 2) exceed those for **2** by approx. two orders of magnitude. Analyzing the LC kinetic data by the Mayr-Patz equation (3) gives $N = 17.78$ ($s_N = 0.81$) for **3a**. Rate constants k_2 for reactions of **3** with all three benzhydryl cations **5a-5c** decrease slightly (by a factor of 3.5-4.5) under conditions of constant ion strength ($I = 1.0$ mM). The resulting N -parameter for **3** is, however, hardly changed at $N = 17.88$ ($s_N = 0.73$). Following the same mode of analysis for **4a** under reactions conditions where $I = 1.0$ mM, we find that anion **4** exceeds the nucleophilicity of **3** by a factor of 3.0 ± 0.5 in its reaction with benzhydryl cations **5a-5c**, which is also reflected in the respective nucleophilicity parameter of $N(\text{4}) = 19.63$ ($s_N = 0.65$).

These measurements thus establish **3a** and **4a** as potent and highly nucleophilic pyridine derivatives in solvents of low polarity (Figure 3). That **4a** is more nucleophilic than **3a** is in full agreement with the results for selected organocatalytic transformations performed in CDCl₃ as the solvent.^[23] The combined methodology developed here thus allows for a quantitative assessment of catalyst nucleophilicity at synthetically relevant concentrations.

Figure 3. Mayr nucleophilicities N (and s_N) of DMAP (**1**), TCAP (**2**), and the pyridinamide anions **3** and **4** (Ani = *p*-methoxyphenyl) in MeCN and DCM.

CONCLUSION

Pyridinamide ion pairs **3a** and **4a** exceed the nucleophilic reactivity of the highly reactive neutral Lewis base TCAP (**2**) by up to two orders of magnitude in DCM. Employing a combination of conductivity and DOSY measurements, we have deciphered an asymmetric association behavior of both pyridinamide ion pairs in the low polarity solvent DCM, which includes both cationic and anionic sandwich complexes but not the commonly assumed and unreactive 1:1 ion pair. Without the combination of conductivity and DOSY measurements this result could not have been achieved since conductivity alone does not give insight into the type of charged species that are being measured. The reactivity of the super-nucleophilic anions **3** and **4** was quantified with the newly developed ionic strength-controlled benzhydrylium ion method, which facilitates the comparison of **3a** and **4a** with neutral nucleophilic catalysts, such as DMAP or TCAP. In DCM, we were able to evaluate kinetic data not only at low ion pair concentrations, but also at synthetically relevant higher concentrations by keeping the ionic strength constant throughout the measurement to prevent the interference of ion association. The direct comparison of k_2 values for reactions with cationic reference electrophiles reveals reactivity values of pyridinamide anions **3** and **4** (at high concentration) that are 39 and 90 times higher than that of TCAP (**2**). The superior reactivity of pyridinamide anions **3** and **4** has recently been observed in catalytic reactions with isocyanates and Michael acceptors as electrophiles^[23,24] This indicates that the higher nucleophilicity of **3** and **4** in comparison to neutral nucleophilic catalysts might be comparably effective for reactions with neutral electrophiles in low polarity media (alkanes, THF, Et₂O). The asymmetric ion association described here, opens the general avenue for employing highly reactive free anions to

activate so far inaccessible substrates in catalytic transformations.

- (38) Note: At concentrations lower than 0.4 mM the experimental values of ion volumes deviate considerably from the theoretical curve. This shows that the equilibrium between free ions and sandwich ion cannot be described by a simple model. However, the concentration limits of DOSY prevent further refinements.

(39) A database of published reactivity parameters E , N , and s_N is freely accessible at <https://www.cup.lmu.de/oc/mayr/reaktionsdatenbank2/> (accessed on 10/09/2024).

(40) Note: For **4a**, where the anionic sandwich **4a4** dominates, the DOSY measurements show that addition of additive **6** (**a**-BF₄) eventually leads to an inversion of the sandwich ion populations towards the cationic **a4a** (see SI, Chapter 4).

2.1 Supplementary Data

2.1.1 General Information

All reagents were purchased from Sigma Aldrich, TCI, or Acros and used without further purification unless otherwise noted. Solvents were obtained from Acros Organics, Sigma Aldrich, or Merck and purified by simple distillation in a rotary evaporator, unless otherwise specified.

All air- and moisture-sensitive reactions were performed under a nitrogen atmosphere and the glassware and magnetic stirrers were dried in a dry oven at 110 °C overnight.

CH₂Cl₂ for nucleophilicity measurements was stirred over concentrated H₂SO₄ for two weeks before extraction with water (1 x 1.0 L), NaHCO₃ (1 x 1.0 L), and again water (1 x 1.0 L). CaH₂ was added as a drying agent, and the solvent was freshly distilled over CaH₂ prior to use.

Melting points were acquired using Büchi Melting Point M-560 devices and are uncorrected.

Nuclear magnetic resonance (NMR) spectra were recorded on a Bruker 400 MHz or INOVA 400 and 600 MHz machines. The following abbreviations were used in the analysis of NMR spectra: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, br s = broad singlet. NMR signals were assigned based on 2D spectra (COSY, HSQC, HMBC, NOESY) experiment analysis. Chemical shifts are given in ppm. The internal reference was set to the residual solvent signals (CD₂Cl₂, CDCl₃, DMSO-d₆). The ¹³C NMR spectra (101 or 151 MHz) were recorded under broadband proton-decoupling. ¹⁹F NMR spectra were referenced using the solvent signal.^[1] The spectra were imported and processed in the program MestreNova (version 14.1.1).

Infrared (IR) spectra were measured on a Perkin Elmer Spectrum BX-59343 instrument with a Smith Detection DuraSamplIR II Diamond ATR sensor for liquids or neat for solids. Intensities are described as vs = very strong, m = medium, w = weak, br = broad.

High-resolution mass spectra (HRMS) were recorded on a Thermo Finnigan LTQ FT Ultra Fourier Transform Ion Cyclotron Resonance mass spectrometer with electrospray ionization (ESI) for sample ionization. For EI (70 eV) measurements a Thermo Finnigan of the MAT 95 type with a direct exposure probe (DEP) was used.

Crystal structures were recorded using an Oxford Diffraction XCalibur with Sapphire CCD-detector and a molybdenum-K_α-source ($\lambda = 0.71073$) with a concentric circle kappa-device. The structures were resolved using the program SHELXS or SIR97 and refined with SHELXS.

2.1.2 Additional Figures and Correlations

Details on data evaluation of conductivity data can be found in Chapter 2.1.4.

Figure 2.1: [Figure S1]. Left: conductivity of **3a** in MeCN (orange points) and in DCM (blue points) at 20 °C with extrapolated conductivity profile of fully dissociated salt (dotted grey line); right: conductivity of **3a** in MeCN (orange points) and fit (black line) of the experimental data according to the 1:1 association model at 20 °C with extrapolated conductivity profile of fully dissociated salt (dotted grey line). Conductivity measurements were performed for concentrations ranging from 0.02 – 2.5 mM but only values in the range 0.02 to 1.0 mM are interpreted as 1.0 mM appears to represent the threshold onset of ion pair formation from the free ions.

The data displayed in Figure 2.1 in the manuscript can be found in Table 2.1

Table 2.1: [Table S1]. List of measured conductivity values (without solvent background conductivity of 0.8 μS cm⁻¹), DOSY measurement results (given as the hydrodynamic volume) and kinetic results for ion pair **3a** in DCM.

2.1.3 Synthesis of Compounds

1,1,1-Trifluoro-*N*-(pyridin-4(1*H*)-ylidene)methanesulfonamide (PA 3)

4-Aminopyridine (2.37 g, 25.2 mmol, 1.0 eq) was dissolved in dry pyridine (30.0 mL) under nitrogen atmosphere. Triethylamine (8.00 mL, 57.4 mmol, 2.3 eq) was added and stirred for 10 min. The reaction mixture was cooled to 0 °C and trifluoromethanesulfonyl chloride (5.00 g, 29.7 mmol, 1.2 eq) was added. After stirring for 10 min at 0 °C, the mixture was refluxed for 3.5 h under nitrogen atmosphere before the solvent was removed. The crude product was suspended in H₂O, refluxed for 20 min and filtered while hot. This process was repeated with acetone and methyl-*tert*-butyl ether (MTBE), yielding pyridinamide **3** (3.55 g, 15.7 mmol, 62%) as a light brown solid.

¹H NMR (400 MHz, DMSO-*d*₆): δ [ppm] = 13.60 (s, 1H), 8.28 (d, *J* = 7.3 Hz, 2H), 7.27 (d, *J* = 7.3 Hz, 2H).

¹³C NMR (101 MHz, DMSO-*d*₆): δ [ppm] = 163.7, 140.2, 120.7 (q, *J* = 325.6 Hz), 116.9.

¹⁹F NMR (377 MHz, DMSO-*d*₆): δ [ppm] = -77.69.

HRMS (ESI): calc. for C₆H₅F₃N₂O₂S⁺ [*M*⁺]: 226.0018, found 226.0019.

4-Methoxy-*N*-(pyridin-4(1*H*)-ylidene)benzenesulfonamide (PA 4)

4-Aminopyridine (2.03 g, 21.6 mmol, 1.0 eq) and NEt₃ (8.50 mL, 61.0 mmol, 2.8 eq) were dissolved in pyridine (22.0 mL). The mixture was cooled to 0 °C and 4-methoxybenzenesulfonyl chloride (5.35 g, 25.9 mmol, 1.2 eq) was added and stirred for 20 min. The reaction mixture was refluxed for 3 h before being cooled down to rt. The solvent was removed, and the resulting precipitate was repeatedly refluxed in H₂O, acetone, and MTBE. The final product was dried *in vacuo*. Pyridinamide **4** (4.78 g, 18.1 mmol, 84%) was obtained as an off-white solid.

¹H NMR (400 MHz, DMSO-*d*₆): δ [ppm] = 12.1 (s, 1H), 8.04 (d, *J* = 6.5 Hz, 2H), 7.74 (d, *J* = 8.9 Hz, 1H), 7.03 (d, *J* = 8.9 Hz, 1H), 6.95 – 6.89 (m, 2H), 3.79 (s, 3H).

¹³C NMR (101 MHz, DMSO-*d*₆): δ [ppm] = 161.7, 151.1, 141.7, 134.4, 128.3, 114.1, 113.8, 55.5.

HRMS (ESI): calc. for C₁₂H₁₂N₂O₃S⁺ [*M*⁺]: 264.0563, found 264.0567.

Tetraphenylphosphonium pyridin-4-yl((trifluoromethyl)sulfonyl)amide (3a)

Pyridinamide **3** (402 mg, 1.78 mmol, 1.0 eq) was added to a solution of NaOH (78.2 mg, 1.96 mmol, 1.1 eq) in H₂O (5.0 mL). Tetraphenyl bromide (746 mg, 1.78 mmol, 1.0 eq) was added, and the reaction mixture was stirred at rt. for 1 h. DCM (5.0 mL) was added, and the two phases were separated. The aqueous phase was extracted with DCM (3 x 15 mL). The collected organic phase was dried over MgSO₄, filtered and the solvent was evaporated. The crude product was crystallized from DCM overlayed with toluene. Pyridinamide ion pair **3a** (787 mg, 1.39 mmol, 78%) was obtained in form of colorless needles.

¹H NMR (400 MHz CDCl₃): δ [ppm] = 8.05 – 8.00 (m, 2H), 7.88 – 7.81 (m, 4H), 7.71 (td, *J* = 7.9, 3.6 Hz, 4H), 7.55 (ddd, *J* = 13.0, 8.4, 1.3 Hz, 4H), 7.02 – 6.97 (m, 2H).

¹³C NMR (101 MHz, CDCl₃): δ [ppm] = 156.1, 149.5, 135.9 (d, *J* = 3.1 Hz), 134.5 (d, *J* = 10.3 Hz), 130.9 (d, *J* = 12.9 Hz), 122.2 (q, *J* = 328.6 Hz), 118.0 (d, *J* = 6.4 Hz), 117.1.

¹⁹F NMR (377 MHz, CDCl₃): δ [ppm] = -76.8.

³¹P NMR (162 MHz, CDCl₃): δ [ppm] = 23.19.

IR (ATR): ν (cm^{-1}) = 3060 (br), 1588 (m), 1484 (w), 1438 (m), 1317 (s), 1288 (s), 1198 (vs), 1155 (s), 1108 (m), 1000 (m), 832 (w), 723 (m).

Elemental Analysis: $\text{C}_{30}\text{H}_{24}\text{F}_3\text{N}_2\text{O}_2\text{PS}$ (564.56 g/mol): calc. (%) C, 63.82; H, 4.29; N, 4.96; S, 5.68; Found (%): C, 63.79; H, 4.32; N, 5.00; S, 5.45.

HRMS (ESI): calc. for $\text{C}_6\text{H}_4\text{F}_3\text{N}_2\text{O}_2\text{S}^- [\text{A}^-]$: 224.9951; found 224.9948; calc. for $\text{C}_{24}\text{H}_{20}\text{P}^+ [\text{C}^+]$: 339.1297; found: 339.1289.

m. p: 183-185 °C.

Tetraphenylphosphonium ((4-methoxyphenyl)sulfonyl)(pyridin-4-yl)amide (**4a**)

Pyridinamide **4** (501 mg, 1.90 mmol, 1.0 eq) was added to a solution of NaOH (78.9 mg, 1.97 mmol, 1.1 eq) in H_2O (5.0 mL). Tetraphenylphosphonium bromide (795 mg, 1.90 mmol, 1.0 eq) was dissolved in DCM and added dropwise over 30 min through a dropping funnel. The reaction mixture was stirred at rt. for 2 h. More DCM (5.0 mL) was added, and the two phases were separated. The aqueous phase was extracted with DCM (3 x 25 mL). The collected organic phase was dried over MgSO_4 ,

filtered and the solvent was evaporated. The crude product was crystallized from DCM overlaid with toluene and heptane (0.5 mL) while stored in the fridge. Ion Pair **4a** (782 mg, 1.30 mmol, 69%) was obtained in form of colorless crystals.

^1H NMR (600 MHz, CDCl_3): δ [ppm] = 7.90 – 7.79 (m, 1H), 7.77 – 7.69 (m, 1H), 7.61 – 7.53 (m, 1H), 6.79 – 6.72 (m, 4H), 3.74 (s, 3H).

^{13}C NMR (151 MHz, CDCl_3): δ [ppm] = 160.5, 157.9, 148.8, 138.8, 135.9 (d, J = 3.1 Hz), 134.5 (d, J = 10.3 Hz), 130.9 (d, J = 12.9 Hz), 128.7, 117.5 (d, J = 89.5 Hz), 116.3, 113.2, 55.4.

^{31}P NMR (162 MHz, CDCl_3): δ [ppm] = 23.03.

Elemental Analysis: $\text{C}_{36}\text{H}_{31}\text{N}_2\text{O}_3\text{PS}$ (602.69 g/mol): calc. (%) C, 71.74; H, 5.18; N, 4.65; S, 5.32; Found (%): C, 71.35; H, 5.24; N, 4.62; S, 5.77.

Tetraphenylphosphonium tetrafluoroborate (**6**)

Tetraphenylphosphonium bromide (1.05 g, 2.50 mmol, 1.0 eq) was dissolved in water and sodium tetrafluoroborate (276 mg, 2.50 mmol, 1.0 eq) was added in portions. The resulting cloudy suspension was stirred for 2 h at rt. DCM (10 mL) was added, and the two phases were separated. The aqueous phase was extracted with DCM (3 x 20 mL).

The collected organic phase was dried over MgSO_4 , filtered and the solvent was evaporated. The crude product was dissolved in DCM and precipitated by adding toluene. Product **6** (940 mg, 2.21 mmol, 88%) was obtained as colorless needles.

^1H NMR (400 MHz, CD_2Cl_2): δ [ppm] = 7.98 – 7.87 (m, 4 H), 7.81 – 7.72 (m, 8 H), 7.66 – 7.56 (m, 8 H).

^{13}C NMR (101 MHz, CD_2Cl_2): δ [ppm] = 36.2 (d, J = 3.3 Hz), 134.8 (d, J = 10.4 Hz), 131.0 (d, J = 13.0 Hz).

^{19}F NMR (377 MHz, CD_2Cl_2): δ [ppm] = -153.43.

^{31}P NMR (162 MHz, CD_2Cl_2): δ [ppm] = 23.12.

IR (ATR): ν (cm^{-1}) = 1586 (w), 1436 (m), 1108 (m), 1052 (s), 750 (w), 689 (s).

Elemental Analysis: $\text{C}_{24}\text{H}_{20}\text{BF}_4\text{P}$ (426.20 g/mol): calc. (%) C, 67.64; H, 4.73; Found (%): C, 67.58; H, 4.62.

HRMS (ESI): calc. for $\text{BF}_4^- [\text{A}^-]$: 87.0035; found: 87.0034; calc. for $\text{C}_{24}\text{H}_{20}\text{P}^+ [\text{C}^+]$: 339.1297; found: 339.1292.

m. p: 350-352 °C.

2.1.4 Conductometric Measurements

2.1.4.1 Sample Preparation and Data Acquisition

For the measurement, an 0.02 M solution of the respective catalyst is prepared in a 10 mL volumetric flask and is given portion-wise to the pure solvent in a measuring cell at 20 °C. Conductivity measurements were done using a WTW conductometer with a Pt electrode LTA 1/NS in MeCN and DCM. Calibration was done as described in ref. [3]. Temperature control (20.0 ± 0.1 °C) was achieved by using a circulating bath cryostat. The conductivity is measured in volts (V) and depicted in “ME-REDLab Data Acquisition V1.1”, developed by Dr. B. Kempf 2010, where the conductivity is plotted against time. After adding a portion of salt stock solution, one must wait until the conductivity value reaches a stable plateau (min 30 sec up to 100 sec) from which the average conductivity value is read off. In Excel this value (V) is then converted into ($\mu\text{S cm}^{-1}$) by multiplying it with the cell parameter of the used electrode ($z = 160$). The cell parameter was obtained by calibrating the conductometric set up with aqueous KCl solutions (0.007 M, 0.0145 M, and 0.0375 M; commercial conductivity standard solutions purchased from Alfa Aesar) referring to the conductivity of $1273 \mu\text{S/cm}$ for an 0.01 M solution of aq. KCl at 20 °C.^[4]

2.1.4.2. Data Analysis – 1:1 Association Model

The conductivity of a substance is defined as its ability to conduct electricity and depends on the number of charge carriers in solution. Therefore, it can be expressed as a molar quantity where κ is the measured conductivity, Λ_m is the molar conductivity and c is the measured concentration of electrolyte.

$$\kappa = \Lambda_m c \quad (2.1)$$

Analysis of the conductivity profile shown in Figure S2 can most easily be approached assuming the formation of a 1:1 ion pair system with concentration [IP] from diffusively free anions A and cations C. For this situation the association constant K_{IP} is given by eq. 2.2.

$$K_{IP} = \frac{[IP]}{[A][C]} \quad (2.2)$$

The combination of eq. 2.2 with eq. 2.3 for the ion pair concentration yields eq. 2.4, which relates the concentration of free ions [A] to the total salt concentration $[IP]_{\text{tot}}$ and the association constant K_{IP} .

$$[IP] = [IP]_{\text{tot}} - [A] \quad (2.3)$$

$$[A] = [C] = \frac{-1 + \sqrt{1 + 4K_{IP}[IP]_{\text{tot}}}}{2K_{IP}} \quad (2.4)$$

The experimentally determined conductivity κ depends on the specific molar conductivity Λ_m and the ion concentration [A] as expressed in eq. 2.5, whose combination with eq. 2.4 the combination of which then yields eq. 2.6.

$$\kappa = \Lambda_m [A] \quad (2.5)$$

$$\kappa = \Lambda_m \times \left\{ \frac{-1 + \sqrt{1 + 4K_{IP}[IP]_{\text{tot}}}}{2K_{IP}} \right\} + \text{BG} \quad (2.6)$$

The value for the specific molar conductivity Λ_m for the combined ions of salt **3a** is derived from the extrapolated linear regression line of the red-marked conductivity values (first three points). The background conductivity (BG) included here is the conductivity of the used solvent ($\text{BG} = 0.80 \mu\text{S cm}^{-1}$).

Figure 2.2: [Figure S2]. Concentration-dependent conductivity profile for catalyst **3a** in DCM with $\Lambda_m = 79.2 \text{ S cm}^2 \text{ mol}^{-1}$ and solvent background BG = $0.8 \mu\text{S cm}^{-1}$ at 20°C .

Eq. 2.6 was used in the fitting program “ProFit7” (version 7.0.18) to obtain the ion pairing constant K_{IP} from the conductivity profiles measured in DCM and MeCN. The specific molar conductivity Λ_m was extrapolated using the first three data points in DCM and the first eight data points in MeCN. The results are collected in Table 2.2.

Table 2.2: [Table S2]. Association constants K_{IP} of ion catalyst **3a** in MeCN and DCM according to eq. 2.6 at 20°C .

Ion Pair	$K_{IP} (\text{M}^{-1})$	
	MeCN [45.6] ^a	DCM [40.7] ^a
3a	34.6 ± 0.3	828 ± 8.27

[a] $E_T(30)$ [kcal mol^{-1}] solvent polarity parameters taken from Reichardt^[5].

In a second approach the complex pathway simulation program, COPASI^[6], was used to numerically analyze the obtained conductivity data. After starting COPASI, a biochemical model was chosen and the association of a single anion **A** reacting with a single cation **C** into the ion pair **IP** was added as reaction (see Scheme 2.1).

Scheme 2.1: [Scheme S1]. Equation for numerical simulations of 1:1 ion association for salt **3a**.

The reaction was set to be reversible, which is also indicated by the equal sign “=” in the reaction equation. In the “Symbol Definition” section the starting compound (A + C) is listed with rate constant k_1 as well as the product (IP) with rate constant k_2 , defining the ion pairing constant as $k_1/k_2 = K_{IP}$.

To find the ion pairing constant $K_{IP} (\text{M}^{-1})$ that best fits our experimental data in the section “Reactions” the reaction constant k_2 was set to be 1, while the rate constant k_1 was changed until the best fit between the simulated and experimental conductivity curve was found.

In the section “Species” the individual concentration for all compounds was added. This would be zero for the 1:1 ion pair **IP** and the first measured total salt concentration of the anion **A** and for the cation **C** (in this example 1.78×10^{-5} M).

<div> <div>COPASI</div> <div> <div>Model</div> <div> <div>Biochemical</div> <div> <div>Compartments [1]</div> <div>Species [3]</div> <div>Reactions [1]</div> <div>ionpairing</div> <div>Global Quantities [0]</div> <div>Events [0]</div> <div>Parameter Overview</div> <div>Parameter Sets [0]</div> </div> </div> </div> </div>		Search: <input type="text"/>				
#	^	Name	Compartment	Type	Unit	Initial Concentration [Unit]

The obtained values for **[A]**, **[C]**, and **[IP]** were copied into an Excel analysis sheet, that contains all relevant data. The obtained concentrations for those three species were then converted into conductivity values according to eq. 2.5. Therefore, the solvent conductivity background of $0.8 \mu\text{S cm}^{-1}$ was subtracted from the measured conductivity values. The molar conductivity Λ_m can be divided into the limited molar conductivity λ_i of each single ionic species i in solution according to eq. 2.7.

$$\Lambda_m = \lambda_A + \lambda_C \quad (2.7)$$

Since the concentration of both ionic species **A** and **C** is always identical in this association model, the individual conductivity contributions are not of critical importance. For now, we assumed that the single anion **A** and the single cation **C** contribute equally to the total molar conductivity Λ_m , that was extracted from region I of the conductivity profile. The 1:1 ion pair **IP** was assigned zero contribution to the molar conductivity Λ_m . The conductivity value of each species is summed up and the final value is compared to the experimental value. This step is repeated until the simulated and experimental conductivity value are close to identical.

This procedure can be tremendously sped up by the use of a Python script that automatically performs the “steady state” function for any given numbers of concentrations.^[7] The “root mean square error” (RMSE) is kept as a control measure and k_1 is optimized until the minimum RMSE for the chosen concentration range is found (which, in some cases, includes up to 5 decimal places). With the assistance of the Python script, we can examine all measured conductivity values right from the start to find the association constant K_{IP} .

The 1:1 association model is the simplest model that can be applied and is usually the first model that is tested for the analysis of the association of a newly designed salt.

By comparing the solutions for the association constant K_{IP} found with the integrated method and the numerical simulations performed with COPASI no difference could be observed (see Figure 2.3).

Figure 2.3: [Figure S3]. Comparing results of integrated method (purple dotted-dashed line) and numerical simulation according to 1:1 ion association model (grey line) for conductivity data of salt **3a**.

The RMSE values do not differentiate as well as the percentage residual between the experimental data and simulated conductivity values. Therefore, we conclude that the two methods can be used interchangeably for the determination of the ion association constant K_{IP} .

2.1.4.3 Double Ion Pair Association Model

DOSY measurements revealed a deviation from the previously assumed 1:1 association model. Instead, we presume an aggregate formation where two cations with one anion form a triple cation ion complex, leaving one anion free. Here, four charged ions associate into two charged species. To compare this “sandwich” association type with the classical 1:1 model on equal footing, the existing model was modified to involve four ions combining into two separate charge-neutral ion pairs (see Scheme 2.2).

Scheme 2.2: [Scheme S2]. Equation for numerical simulations of double 1:1 ion association for salt **3a**.

The above detailed procedure was followed to determine and optimize the ion pairing constant K_{IP} (M^{-2}). The final result was found to be $K_{IP} = 6.86 \times 10^5 M^{-2}$ for pyridinamide ion pair **3a** in DCM.

2.1.4.4 Sandwich Association Model

With DOSY measurements, it was determined that instead of the previously assumed simple 1:1 association of anion and cation, a “sandwich cation” aggregate form first. This new insight necessitates a reconsideration of the previously applied association model. Since a mathematical description of this new association model has not yet been achieved, the software COPASI was utilized for the numerical analysis of this newly derived model. The association of two single anions **A** and cations **C** into the sandwich cation **CAC** and one free **A** (see Scheme 2.3) was numerically simulated using COPASI.

Scheme 2.3: [Scheme S3]. Equation for numerical simulations of newly derived cationic sandwich association model for salt **3a**.

The reaction was selected to be reversible. The sandwich association constant is defined as $k_1/k_2 = K_{\text{CAC}}$ with $k_2 = 1$ being a fixed value.

2.1.4.4.1 Model 1

The procedure to find the best fitting sandwich association constant K_{CAC} is identical to the one described for the 1:1 association model. However, when converting the obtained concentration of each species, anion **A**, cation **C**, and sandwich-cation **CAC**, into conductivity values, the contribution of each species towards the molar conductivity is critical. Through literature search, we found the limited molar ionic conductivity λ_{NBu_4} of tetrabutylammonium cation (NBu_4^+ , **b**) to be $45.5 \text{ S cm}^2 \text{ mol}^{-1}$,^[8] which is also part of our pyridinamide ion pair library in combination with anion **3**, giving pyridinamide ion pair **3b** (see Scheme S4).

Scheme 2.4: [Scheme S4]. Structure of pyridinamide ion pair **3b**.

By recording the conductivity profile **3b** in DCM, its molar conductivity was identified to be $57.9 \text{ S cm}^2 \text{ mol}^{-1}$ (see Figure 2.4, red-marked initial three points for extrapolation of Λ_m).

Figure 2.4: [Figure S4]. Concentration-dependent conductivity profile for catalyst **3b** in DCM with $\Lambda_m = 57.9 \text{ S cm}^2 \text{ mol}^{-1}$ without solvent background at 20°C .

By subtracting the limited molar ionic conductivity λ_{NBu_4} of NBu_4^+ from the molar conductivity Λ_m of salt **3b**, the limited molar ionic conductivity λ_{an3} of anion **3** is determined to be $\lambda_{\text{an3}} = 11.4 \text{ S cm}^2 \text{ mol}^{-1}$. Since the molar conductivity of salt **3a** is $79.2 \text{ S cm}^2 \text{ mol}^{-1}$ in DCM, it can be concluded that the limited molar ionic conductivity of cation **a** is $\lambda_{\text{PPH}_4} = 67.8 \text{ S cm}^2 \text{ mol}^{-1}$. This translates to a contribution of 14% for the anion **A** and 86% for the cation **C** towards the total molar conductivity Λ_m of salt **3a**. Next, it is necessary to evaluate the contribution of the sandwich cation to the overall molar conductivity Λ_m of $79.2 \text{ S cm}^2 \text{ mol}^{-1}$.

According to literature, it is common to assume a specific quotient for the limited molar conductivity of the sandwich-cation ($\lambda_{\text{CAC}}/\Lambda_m$). Most often the quotient is assumed to be $1/3$ ^[9–11], $2/3$ ^[12], or $(1/3)^{(1/3)} = 0.693$ ^[13,14]. The quotient $\lambda_{\text{CAC}}/\Lambda_m = (1/3)$ was used for different salts, like lithium and tetrabutylammonium thiocyanates^[10] or 1-ethyl-3-methylimidazolium tetrafluoroborate and 1-butyl-3-

methylimidazolium tetrafluoro borate^[11], in various solvents. The quotient $\lambda_{\text{CAC}}/\Lambda_m = (1/3)^{(1/3)}$ was mainly used to describe the fluoroalkanoates and triethylamine chlorides in polar solvents as MeCN. Meanwhile, the quotient $\lambda_{\text{CAC}}/\Lambda_m = 2/3$ has been used for the analysis of tetraphenyl boron salts in THF, which is another spheric ion in a nonpolar solvent.^[12] Therefore, it serves as the best reference for our system **3a**. So, for the future analysis of equilibria with sandwich cation formations in DCM, the quotient $\lambda_{\text{CAC}}/\Lambda_m = \delta_{\text{CAC}} = 2/3$ will be used. Here, we introduce δ_i as *scaling factor* for the conversion of Λ_m into the respective λ_i . The final result for the sandwich association constant with 14% anion contribution, 86% cation contribution and 2/3 sandwich cation contribution would be $K_{\text{CAC}} = 2.62 \times 10^6 \text{ M}^{-2}$ for pyridinamide ion pair **3a** in DCM with an RMSE = 0.62 (see Table 2.3).

Table 2.3: [Table S3]. Association constant K_{CAC} for pyridinamide ion pair **3a** according to model 1 with the respective limited molar ionic conductivities λ_i .

λ_A (S cm ² mol ⁻¹)	λ_C (S cm ² mol ⁻¹)	λ_{CAC} (S cm ² mol ⁻¹)	K_{CAC} (M ⁻²)	RMSE
$0.14 \times \Lambda_m$	$0.86 \times \Lambda_m$	$(2/3) \times \Lambda_m$	2.62×10^6	0.62

2.1.4.4.2 Model 2

a) Cationic Sandwich Association (Model 2a)

The recent DOSY result, however, made us question if conventional conductivity measurements are able to measure solutions of high enough dilution to guarantee fully dissociated ions. Therefore, we decided on a second approach toward the determination of the sandwich association constant based on the conductivity measurements, where the ratio between the anion and cation contribution to the molar conductivity Λ_m is treated as a second variable parameter. Since the model always starts from fully dissociated ions the sum of the scaling factors $\delta_A + \delta_C$ cannot exceed 1. The contribution of the sandwich cation was still set to be $2/3\Lambda_m$. Different ratios for δ_A/δ_C were tested and the full analysis to find K_{CAC} was done. Then the RMSE value for this sandwich association constant was compared (see Table 2.4).

Table 2.4: [Table S4]. List of optimization steps for limited molar ionic conductivities λ_i with the corresponding association constants K_{CAC} for pyridinamide ion pair **3a** according to model 1.

λ_A (S cm ² mol ⁻¹)	λ_C (S cm ² mol ⁻¹)	λ_{CAC} (S cm ² mol ⁻¹)	K_{CAC} (M ⁻²)	RMSE
$0.14 \times \Lambda_m$	$0.86 \times \Lambda_m$	$(2/3) \times \Lambda_m$	2.62×10^6	0.620
$0.30 \times \Lambda_m$	$0.70 \times \Lambda_m$		$4.0 \times 10^6 - 5.0 \times 10^6$	<0.35
$0.33 \times \Lambda_m$	$0.67 \times \Lambda_m$		5.20×10^6	0.210
$0.35 \times \Lambda_m$	$0.65 \times \Lambda_m$		5.70×10^6	0.183
$0.36 \times \Lambda_m$	$0.64 \times \Lambda_m$		5.97×10^6	0.175
$0.37 \times \Lambda_m$	$0.63 \times \Lambda_m$		6.27×10^6	0.173
$0.38 \times \Lambda_m$	$0.62 \times \Lambda_m$		6.57×10^6	0.176
$0.40 \times \Lambda_m$	$0.60 \times \Lambda_m$		7.31×10^6	0.200

The best fit was found for $K_{\text{CAC}} = 6.27 \times 10^6 \text{ M}^{-2}$ with a RMSE = 0.17, which is the final result for the sandwich association constant of pyridinamide ion pair **3a**.

Both equilibrium constants were used to determine the percentage speciation (see Table 2.5 and 2.6).

Table 2.5: [Table S5]. Speciation of pyridinamide ion pair **3a** in 1:1 model in DCM with $K_{\text{IP}} = 6.86 \times 10^5 \text{ M}^{-2}$ and their percentage.

8.80 x 10 ⁻⁴	5.83 x 10 ⁻⁴	2.85 x 10 ⁻⁴	2.97 x 10 ⁻⁴	0.66	0.32	0.34
9.44 x 10 ⁻⁴	6.17 x 10 ⁻⁴	2.91 x 10 ⁻⁴	3.27 x 10 ⁻⁴	0.65	0.31	0.35
1.01 x 10 ⁻³	6.53 x 10 ⁻⁴	2.95 x 10 ⁻⁴	3.57 x 10 ⁻⁴	0.65	0.30	0.35

In both association models the anion and cation are mainly dissociated at low concentrations. While in the 1:1 model the concentration of anion and cation are always identical, in the sandwich association the concentration of free cation [C] is faster declining than the concentration of free anion [A] due to the formation of the sandwich cation. In both association model the concentration of free anion [A] is 65% and available to react as nucleophilic catalyst in solution.

The ion pair **4a** and additive **6** were analyzed the same way as pyridinamide salt **3a** with the two-parameter approach (model 2) for the sandwich association constant K_{CAC} . The results can be found in Table 2.7.

Table 2.7: [Table S7]. Association constants K_{IP} and K_{CAC} according to the respective biochemical models of ion catalysts **3a**, **4a**, and additive **6** at 20 °C in DCM.

Ion Pair	$K_{IP} (M^{-2})$	$K_{CAC} (M^{-2})$
3a	6.86×10^5	6.27×10^6
4a	8.79×10^5	6.71×10^6
6	1.01×10^6	7.28×10^6

b) Anion Sandwich Association (Model 2b)

Aside from the previously discussed cationic sandwich association, the contrasting anionic sandwich association leading to a free cation **C** and a sandwich anion **ACA**, which consists of two anions **A** and one central cation **C**, is equally thinkable. For the analysis of this association type, we applied the same numerical model as discussed earlier using COPASI (see Scheme 2.5).

Scheme 2.5: [Scheme S5]. Equation for numerical simulations of anionic sandwich association model for salt **3a**.

The anion sandwich association constant is defined as $k_1/k_2 = K_{ACA}$ with to $k_2 = 1$ being a fixed value. The contribution of the sandwich anion was also set to be $2/3 * \Lambda_m$. Different ratios for $\lambda_A + \lambda_C$ were tested, and numerical simulation were performed until the best association constant K_{ACA} was found. The RMSE value for the anion sandwich association constant K_{ACA} was used as a quality control measure.

Following the above-described guideline for model 2 resulted in exactly the same anion sandwich association constant as the cationic sandwich association with $K_{ACA} = K_{CAC} = 6.27 \times 10^6 M^{-2}$. This was to be expected since the individual ionic conductivity contributions λ_i towards the overall molar conductivity Λ_m are treated as variables here, while the sandwich ion contribution λ_i is fixed to be $2/3 * \Lambda_m$. Therefore, the molar ionic conductivity contributions interchanged by moving from the cationic sandwich association to the anionic sandwich association (see Table 2.8).

Table 2.8: [Table S8]. Association constants K_{CAC} and K_{ACA} for pyridinamide ion pair **3a** according to model 2 with the respective limited molar ionic conductivities λ_i .

Sandwich Type	λ_A (S cm ² mol ⁻¹)	λ_C (S cm ² mol ⁻¹)	$\lambda_{i=CAC,ACA}$ (S cm ² mol ⁻¹)	$K (M^{-2})$	RMSE
Cationic	$0.37 \times \Lambda_m$	$0.63 \times \Lambda_m$	$(2/3) \times \Lambda_m$	6.27×10^6	0.17
Anionic	$0.63 \times \Lambda_m$	$0.37 \times \Lambda_m$	$(2/3) \times \Lambda_m$	6.27×10^6	0.17

To conclude, based on the conductivity data, we cannot determine with certainty which type of sandwich ion association is favored.

2.1.4.4.3 Model 3

a) Cation Sandwich Association (Model 3a)

Further development of the conductivity model led to the following changes. We specifically focused on how we determine the contribution made towards the molar specific conductivity Λ_m by each of the charged species. Fuoss *et al.* stated that the limited molar ionic conductivity λ of each ion is proportional to their volume.^[15,16] Therefore, we applied this approach by using the calculated cavity volumes of each anion, cation, and ion pair to calculate the percentage share of the anion volume **A** and cation volume **C** (see eq. 2.8), which will then be used as scaling factors δ_i to convert Λ_m into the respective λ_i .

$$\delta_A = \frac{\text{vol}(\text{A})}{\text{vol}(\text{IP})} \quad (2.8a)$$

$$\delta_C = \frac{\text{vol}(\text{C})}{\text{vol}(\text{IP})} \quad (2.8b)$$

Here, the calculated volumes of anion **3** (215 Å³), cation **a** (362 Å³), and contact ion pair **3a** (570 Å³), which are based on the van der Waals cavities employed in the SMD continuum solvation model at the SMD(DCM)/B3LYP-D3/6-31+G(d) level of theory are used (see Table 2.16). Since there is no known way to determine the limited molar ionic conductivity λ_{CAC} for the cation sandwich in DCM, we decided to treat it as another variable instead of assigning a set value to it. This refined approach gives us the following results for the cationic sandwich association (see Table 2.9). All scaling factors δ_i are limited to two decimals, when used in the excel sheet to transform concentration into conductivity values.

Table 2.9: [Table S9]. Association constant K_{CAC} for salt **3a**, **4a**, and **6** according to model 3a with the respective limited molar ionic conductivities λ_i and the scaling factors δ_i .

Ion Pair	Λ_m (S cm ² mol ⁻¹)	λ_A (S cm ² mol ⁻¹)	λ_C (S cm ² mol ⁻¹)	$\delta_A/\delta_C/\delta_{\text{CAC}}$	K_{CAC} (M ⁻²)	RMSE
3a	79.2	29.3	49.9	37/63/67	6.38 x 10 ⁶	0.17
4a	73.6	32.4	41.2	44/56/54	6.50 x 10 ⁶	0.12
6	95.2	15.2	80.0	16/84/80	7.05 x 10 ⁶	0.16

Comparing the results from model 2 with model 3 show only small deviations between the obtained sandwich association constants K_{CAC} .

b) Anion Sandwich Association (Model 3b)

The analysis of the conductivity data according to model 3 for the anion sandwich association gives the same value for the anionic sandwich association constant K_{ACA} as for the cationic sandwich association with $K_{\text{ACA}} = K_{\text{CAC}} = 6.38 \times 10^6 \text{ M}^{-2}$ for ion pair **3a** and $K_{\text{ACA}} = K_{\text{CAC}} = 6.50 \times 10^6 \text{ M}^{-2}$ for ion pair **4a**. The results are summarized in Table 2.10.

Table 2.10: [Table S10]. Association constant K_{ACA} for salt **3a** and **4a** according to model 3b with the respective limited molar ionic conductivities λ_i and the scaling factors δ_i .

Ion Pair	Λ_m (S cm ² mol ⁻¹)	λ_A (S cm ² mol ⁻¹)	λ_C (S cm ² mol ⁻¹)	$\delta_A/\delta_C/\delta_{\text{ACA}}$	K_{ACA} (M ⁻²)	RMSE
3a	79.2	29.3	49.9	37/63/41	6.38 x 10 ⁶	0.17
4a	73.6	32.4	41.2	44/56/42	6.50 x 10 ⁶	0.12

Thus, both sandwich association types are not distinguishable based on conductivity data alone. Therefore, we need to look at the DOSY measurements to gain an understanding of which association type is a better fit for each respective ion pair.

2.1.4.5 Mixed Sandwich Association (Model 4)

So far, we have separately analyzed the conductivity data for both cationic and anionic sandwich association. However, the comparison between the simulated DOSY volumes based on the numerical simulation of conductivity data for both association types and the experimentally determined DOSY volumes revealed significant deviations (see Figure 2.5).

Figure 2.5: [Figure S5]. Concentration-dependent volumes of cations **a** (orange “+” symbols) and anions **3** (green “-” symbols) of salt **3a** in CD₂Cl₂ as calculated from DOSY experiments (with data from ref [2]) with the respective free ion volumes (dotted line; cation in orange; anion in green), the simulated trend for the cationic (grey line) and anionic (blue dashed line) sandwich model.

To minimize this deviation, we extended our earlier described conductivity model 3. Since the resulting association constant was identical for both the cationic and anionic sandwich associations under model 3, the idea was to combine both sandwich association types into one model, which we will refer to as the *mixed association model* moving forward.

Scheme 2.6: [Scheme S6]. Cation sandwich association and anion sandwich association model for pyridinamide ion pair **3a**.

To find the right balance between the cation sandwich association and the anion sandwich association each association constant was assigned a *scaling factor*, which would be multiplied with the respective sandwich association constant whereas, where α would be a fixed value decreasing from 1.0 in steps of 0.1 (see eq. 2.9)

$$K_{CAC} \times \alpha \quad (2.9a)$$

$$K_{ACA} \times \beta \quad (2.9b)$$

For each step the best β value with the smallest RMSE for the conductivity data was determined by employing numerical simulations. The optimization of the scaling factor was limited to two relevant decimals.

Table 2.11: [Table S11]. List of association constants based on the optimized scaling factors α and β with the calculated anion and cation volumes (\AA^3) and the respective percentual residual between the reference ion volume and calculated ion volume for pyridinamide ion pair **3a**.

This routine was repeated with β as the fixed factor and α as the factor to be optimized, ensuring compliance between both approaches, as shown in Figure 2.6.

Figure 2.6: [Figure S6]. Graphical representation of the ratio of the optimized scaling factors α and β with α being the fixed value for the optimization of β (grey dots) and in reverse β being the fixed value for the optimization of α (blue dots) for pyridinamide ion pair **3a**.

The two data sets are almost identical with small deviations especially in the outer regions where one factor is significantly larger than the other. Therefore, the performance of each optimization step based on both scaling factors α and β is crucial since each chosen fix point offers a unique point of view onto the ideal sandwich association mixture. The zenith is found at $\alpha = \beta = 0.315$ with $K_{\text{CAC}} = K_{\text{ACA}} = 2.01 \times 10^6 \text{ M}^{-2}$.

The next step involved incorporating experimental DOSY data by using the experimental DOSY volumes of ion pair **3a** as a reference value (with $V_{\text{an}} = 505 \text{ \AA}^3$ and $V_{\text{cat}} = 642 \text{ \AA}^3$). Numerical simulations provided concentrations used to calculate simulated DOSY volumes (see eq. 2.10).

$$\text{vol}_{\text{cat}} = \frac{[\text{C}]}{[\text{IP}]_{\text{tot}}} \times 362 + \left(\frac{2 \times [\text{CAC}]}{[\text{IP}]_{\text{tot}}} \right) \times 925 + \left(\frac{[\text{ACA}]}{[\text{IP}]_{\text{tot}}} \right) \times 782 \quad (2.10a)$$

$$\text{vol}_{\text{an}} = \frac{[\text{A}]}{[\text{IP}]_{\text{tot}}} \times 215 + \left(\frac{[\text{CAC}]}{[\text{IP}]_{\text{tot}}} \right) \times 925 + \left(\frac{2 \times [\text{ACA}]}{[\text{IP}]_{\text{tot}}} \right) \times 782 \quad (2.10b)$$

Subsequently, the percentual residual between experimental and simulated ion volumes determined the optimal mix of cationic and anionic sandwich association, showing that $\alpha = \beta = 0.44/0.21$ for ion pair **3a** was optimal (see Table 2.12). The previous optimization steps of α and β indicates in what region further optimization steps need to be taken e.g. for ion pair **3a** additional optimization was done starting from $\alpha/\beta = 0.47/0.20$.

Table 2.12: [Table S12]. List of association constants based on the optimized scaling factors α and β with the calculated anion and cation volumes (\AA^3) and the respective percentual residual between the reference ion volume and calculated ion volume with focus on the area around the smallest percentual residue for both ion volumes for **3a**.

Comparing the simulated DOSY data based on Model 3 for the cationic and anionic sandwich association with the newly introduced mixed model demonstrated a significant improved overlap with experimental data than any other association model (see Figure 2.7).

Figure 2.7: [Figure S7]. Concentration-dependent volumes of cation **3a** (orange “+” symbols) and anion **3** (green “-” symbols) of salt **3a** in CD_2Cl_2 as calculated from DOSY experiments (with data from ref [2]) with the respective free ion volumes (dotted line; cation in orange; anion in green), the simulated trends for the cationic (grey line) and anionic (blue dashed line) sandwich model, and the mixed sandwich association model (brown short-dashed line).

This procedure was repeated for pyridinamide ion pair **4a**. The results of the mixed model analysis are summarized in Table 2.13.

Table 2.13: [Table S13]. Specific molar conductivity Λ_m , the scaling factors δ_i and association constants K_{CAC} and K_{ACA} with their respective scaling factor α and β for pyridinamide ion pair **3a** and **4a**.

Ion Pair	Λ_m (S cm ² mol ⁻¹)	$\delta_A/\delta_C/\delta_{CAC}/\delta_{ACA}$	$\alpha \times K_{CAC}$ (M ⁻²)	$\beta \times K_{ACA}$ (M ⁻²)	α/β (%)	RMSE
3a	79.2	37/63/67/41	2.81×10^6	1.34×10^6	44/21	0.43
4a	73.6	44/56/54/42	7.80×10^5	3.97×10^6	12/61	0.35

The resulting association constants of the mixed model analysis for pyridinamide ion pair **3a** and **4a** were used to determine the percentage speciation (see Table 2.14 and Table 2.15).

Table 2.14: [Table S14]. Speciation of pyridinamide ion pair **3a** in model 4 with $\alpha \times K_{CAC} = 2.81 \times 10^6$ M⁻² and $\beta \times K_{ACA} = 1.34 \times 10^6$ M⁻² ($\alpha/\beta = 0.44/0.21$), and the percentage of each involved charged species.

For both pyridinamide ion pair mainly dissociated anion and cation were shown at low concentrations.

At 1.0 mM salt concentration, the association of pyridinamide ion pair **3a** still showed 50% of free anion in solution which acted as reactive nucleophile. Meanwhile, pyridinamide ion pair **4a** only has 35% free anion at 1.0 mM since here the anionic sandwich association is more pronounced. This, however, was no concern in the nucleophilicity measurement since DOSY NMR tests revealed a shift in ion volumes for mixtures of **4a** with additive **6** (for details see Chapter 2.1.5).

2.1.4.6 Workflow summary

The above detailed workflow for the determination of ion pairing constant K_{IP} and sandwich association constant K_{CAC}/K_{ACA} , and the composition of mixed model for pyridinamide ion pairs based on conductivity measurements in DCM, can be summarized in the following steps:

Determination of Ion Pairing constant K_{IP} for salt **3a**

- Measure conductivity for **3a**.
- Determine the molar conductivity Λ_m by linear extrapolation of the first three data points.
- Use eq. 2.6 or the respective biochemical model (for details see Scheme 2.1 or 2.2) concentrations for all compound involved in the model, copy the concentrations into Excel to convert them into conductivity values by assigning both ion 50% contribution towards Λ_m .
- Compare sum of theoretical conductivity with experimental values (without solvent background conductivity).
- Use the RMSE value as a quality control measure.
- Adjust k_1 in $K_{CAC} = k_1/k_2$ until the minimum RMSE is found, to obtain K_{IP} .

Determination of cationic and anionic sandwich association constant K_{CAC} or K_{ACA} for salt **3a** (Model 3)

- Measure conductivity for **3a**.
- Determine the molar conductivity Λ_m by linear extrapolation of the first three data points.
- Set the limited molar ionic conductivity for the anion λ_A and cation λ_C to the calculated values of the scaling factor δ_i based on eq. 2.8. The sum of $\delta_A + \delta_C$ cannot exceed 1.
- Treat $\delta_{CAC} = \lambda_{CAC}/\Lambda_m(\mathbf{3a})$ as a second variable. Select at starting value e.g. $\delta_{CAC} = 0.67$ and start the optimization process for K_{CAC} .
- Use the respective sandwich association model (Model 3) to obtain concentrations for all species involved, copy them into Excel to convert them into conductivity values using eq. 2.5.

- l) Compare sum of theoretical conductivity with experimental values (without solvent background conductivity).
- m) Use the RMSE values as a quality control measure.
- n) Adjust k_1 in $K_{CAC} = k_1/k_2$ until minimum RMSE is found, to obtain the final K_{CAC} .
- o) Adjust the limited molar ionic conductivity for the sandwich ion λ_{CAC} to find the percentual distribution that fits the conductivity data the best. For each new percentual distribution, repeat step k) – n) until the global minimum RMSE is found.

For analysis of the additive **6** follow these steps:

- p) Measure conductivity for **6**.
- q) Follow step i) – o) as described above to obtain K_{CAC} for additive **6**.

Determination of composition of cationic and anionic sandwich association for salt **3a** (Model 4)

After determination of the cationic sandwich association constant K_{CAC} and the anionic sandwich association K_{ACA} the mix of both association types that fits the experimental data best is ascertained.

- r) Assign each association constant a *scaling factor*: $K_{CAC} \times \alpha$ and $K_{ACA} \times \beta$.
- s) Set α to a fixed value starting at 1.0 and going down in steps of 0.1. Optimize β to achieve the smallest RMSE value for the conductivity data using numerical simulations. Limit each factor to two relevant decimals.
- t) Repeat step s) vice versa for factor β .
- u) Determine the composition of cationic and anionic sandwich association in reference to the measured DOSY volume at 1.0 mM by calculating the percentual residual between experimental and simulated ion volumes.
- v) Take further optimization steps until finding the α/β ratio with the smallest percentual residual for both cation and anion volume.

2.1.4.7 Data of Conductivity Measurements in MeCN

Raw data of concentration dependent conductivity profile of **3a** in MeCN at 20 °C

2.1.5 DOSY NMR Measurements

2.1.5.1 Cationic Sandwich Model

The DOSY volumes of compound **3a** were plotted against the salt concentration [**3a**] for both anion **3** and cation **a** (see Figure 2.8). At the lowest concentration ([**3a**] = 0.005 mM and 0.01 mM), volumes that closely matched the calculated values for the free ions (cation **a**: 362 Å³ and anion **3**: 215 Å³, see Table 2.16) were observed. In the 1:1 association model, as the concentration increased, the volumes of both ions were expected to rise and gradually converge, until they became identical at higher concentrations. Hereby, the anion volume would need to increase more rapidly than the cation volume to achieve this convergence, as expected for a 1:1 aggregation.

However, despite an increase in the volumes for both the anion **3** and cation **a** at concentrations higher than 0.01 mM, a significant offset between the cation **a** and the anion **3** volume was observed. The volume of cation **a** increased more than that of anion **3**, leading to a growing offset between the two volumes, contrary to the expected behavior in a 1:1 association, where the volumes of anion and cation should converge and approach 570 Å³ for the monomeric ion pair **3a**. Additionally, in the concentration range of 0.4–1.0 mM, the cation volume plateaued at a value significantly exceeding the calculated monomeric ion pair volume of **3a** (642 Å³ vs. 570 Å³). These observations suggest the involvement of an additional species.

Figure 2.8: [Figure S9]. Concentration-dependent volumes of cation **a** (orange “+” symbols) and anion **3** (green “-” symbols) of salt **3a** in CD₂Cl₂ as calculated from DOSY experiments (with data from ref [2]) with the respective calculated free ion volumes (dotted line; cation **a** in orange; anion **3** in green), and the calculated volumes of the 1:1 ion pair **3a** (purple dotted line).

To account for this deviation, a “sandwich association” model was proposed, in which two cations **a** and one anion **3** form a “sandwich-cation” complex **a3a** with a calculated volume of 925 Å³ (see Table 2.16), along with an additional free anion **3** (calculated volume of 215 Å³). This model explains the increasing offset between the volumes of cation **a** and anion **3** during the ion association, as the free anion reduces the average DOSY anion volume. The higher cation volumes (642 Å³) observed at increasing concentrations can be attributed to the formation of sandwich-cations that are included in the average DOSY cation volume.

The theoretical volumes for the free ions, the 1:1 monomeric ion pair **3a**, and the sandwich model were calculated based on the van der Waals cavity used in the SMD solvation model at the B3LYP-D3/6-31+G(d) level of theory (see Table 2.16).

Table 2.16: [Table S19]. Calculated volumes of all proposed species based on the van der Waals cavity used in the SMD solvation model at the B3LYP-D3/6-31+G(d) level of theory.

Species	Volume (Å ³)
Anion 3	215
Anion 4	285
Cation a	362
1:1 ion pair 3a	570
Cation sandwich a3a	925
Anion sandwich 3a3	782
1:1 ion pair 4a	641
Cation sandwich a4a	995
Anion sandwich 4a4	920

The volumes of the free anion **3** and free cation **a** at a given overall salt concentration were calculated according to eq. 2.11 with the aid of numerical simulation based on the conductivity data (see 1.1.4).

$$\text{vol}_{\text{cat}} = \frac{[\text{C}]}{[\text{IP}]_{\text{tot}}} \times 362 + \left(\frac{2 \times [\text{CAC}]}{[\text{IP}]_{\text{tot}}} \right) \times 925 \quad (2.11a)$$

$$\text{vol}_{\text{an}} = \frac{[\text{A}]}{[\text{IP}]_{\text{tot}}} \times 215 + \left(\frac{[\text{CAC}]}{[\text{IP}]_{\text{tot}}} \right) \times 925 \quad (2.11b)$$

Based on the calculated populations of the respective free ion, the theoretical DOSY volumes were simulated (see Figure 2.9).

**Figure 2.9:** [Figure S10]. Concentration-dependent volumes of cation **a** (orange “+” symbols) and anion **3** (green “-” symbols) of salt **3a** in CD₂Cl₂ as calculated from DOSY experiments (with data from ref [2]) with the simulated trends for the cationic sandwich association model (orange line for cation **a**, green line for anion **3**), and the 1:1 ion association model (orange dotted-dashed line for cation **a**, green dotted-dashed line for anion **3**).

For both ions, the calculated trend for the 1:1 ion aggregation model led to far lower volumes than observed by the DOSY measurements, with discrepancies of up to 250 Å³ (see Figure 2.9). By involving the sandwich cation, the calculated curves fit far better to the observed trends in volume (see Figure 2.10). Therefore, the volumes cannot be explained by a single 1:1 aggregation, but other species such as the sandwich cation **a3a** have to be considered.

Figure 2.10: [Figure S11 + S12]. Concentration-dependent volumes of cations **a** (orange “+” symbols) and anions **3** (green “-” symbols) of salt **3a** in CD_2Cl_2 as calculated from DOSY experiments (with data from ref [2]) with the respective free ion volumes (dotted line; cation in orange; anion in green), the simulated trend for the 1:1 ion association model (purple dotted-dashed line), and cationic sandwich model (grey line).

2.1.5.2 Anionic Sandwich Model

When plotting the DOSY volumes for salt **4a** against the salt concentration [**4a**], a different trend is observed, indicating the presence of an additional species. Unlike **3a**, the volume of anion **4** showed a significantly greater increase than the volume of cation **a** with increasing concentration, and eventually surpassed the cation volume. At 0.005 mM, the determined volumes for anion **4** (296 \AA^3) and cation **a** (403 \AA^3) are close to the calculated volumes of the free ions (anion: 285 \AA^3 and cation: 360 \AA^3 , see Table 2.16). As the concentration increases, both volumes rose, but the anion volume increased more rapidly than the cation volume. This led to a crossover at 0.05 mM, where their volumes were nearly identical, before the volume of anion **4** (765 \AA^3) exceeded that of cation **a** (682 \AA^3). Both the anion and cation volumes exceeded the calculated volume of the monomeric ion pair **4a** (641 \AA^3), suggesting that the formation of a 1:1 ion pair or a sandwich-cation was unlikely. Instead, these trends point towards the formation of another type of aggregate.

Considering the formation of the sandwich-cation for **3a**, a similar aggregate in form of a sandwich-anion was proposed for **4a** involving two anions **4** and one cation **a** in the sandwich-anion complex **4a4**, leaving a free cation **a**. This anionic sandwich association model explains the observed increase in anion volume and the crossing point, as well as the cation volumes that were higher than the calculated volumes of the monomeric ion pair **4a**, since the DOSY volumes display the average volumes of all cationic species in solution.

Figure 2.11: [Figure S15]. Concentration-dependent volumes of cation **a** (orange “+” symbols) and anion **4** (green “-” symbols) of salt **4a** in CD_2Cl_2 as calculated from DOSY experiments (with data from ref [2]) with the respective calculated free ion volumes (dotted line; cation **a** in orange; anion **4** in green), and the calculated volumes of the 1:1 ion pair **4a** (purple dotted line).

Additional experiments with a fixed cation concentration at 1.0 mM were performed. Three different ion pair **4a** concentrations (0.2 mM, 0.5 mM, 0.8 mM) were measured, using additive **6** to maintain the overall ionic strength I at $I = 1.0$ mM (for data see SI of ref [2]). The anionic sandwich association model dictates that the anion volume should decrease with increasing proportion of additive **6** since the formation of the sandwich-anion is less likely to occur with increasing cation concentration. And indeed, the anion volume decreased significantly (from 780 \AA^3 to 576 \AA^3) as the additive portion increased. Meanwhile, the cation volume remained relatively stable (680 \AA^3 to 698 \AA^3), leading to another crossing point where the cation volume exceeded that of the anion (see Figure 2.12). These findings further support the anionic sandwich association model for ion pair **4a**.

Figure 2.12: [Figure S16]. Concentration-dependent volumes of cation **a** (orange “+” symbols) and anion **4** (green “-” symbols) of **4a**/additive **6** mixtures with increasing amounts of **6** at $I = 1.0$ mM in CD_2Cl_2 as calculated from DOSY experiments (with data from ref [2]) with the respective calculated free ion volumes (dotted line; cation **a** in orange; anion **4** in green), and the calculated volumes of the 1:1 ion pair **4a** (purple dotted line), the sandwich cation **4a4** (grey dotted line), and the sandwich anion **4a4** (blue dotted line).

Furthermore, numerical simulations comparing the cationic sandwich association, the anionic sandwich association, the 1:1 ion association, and the mixed sandwich association were conducted and compared to the DOSY data (see Figures 1.11 and Figure 1.12). For ion pair **4a**, the anionic sandwich association model and the mixed association model provided the best fit to the experimental data, whereas the cationic sandwich association model and the 1:1 ion association model showed significantly larger deviations. This further supports the presence of the sandwich anion **4a4** in solution. To conclude, the

mixed sandwich association model, where both types of sandwich complexes coexist, with the anionic sandwich association being the predominate association pattern, provided the best fit between simulation and experimental data.

Figure 2.13: [Figure S17]. Concentration-dependent volumes of cation **a** (orange “+” symbols) and anion **4** (green “-” symbols) of salt **4a** in CD_2Cl_2 as calculated from DOSY experiments (with data from ref [2]) with the respective calculated free ion volumes (dotted line; cation **a** in orange; anion **4** in green), and the calculated volumes of the 1:1 ion pair **4a** (purple dotted line), the sandwich cation **a4a** (grey dotted line), the sandwich anion **4a4** (blue dotted line), and the simulated trend for the mixed sandwich association model (short-dashed line).

Figure 2.14: [Figure S18 + S19]. Concentration-dependent volumes of cation **a** (orange “+” symbols) and anion **4** (green “-” symbols) of salt **4a** in CD_2Cl_2 as calculated from DOSY experiments (with data from ref [2]) with the respective free ion volumes (dotted line; cation in orange; anion in green), the simulated trends for the 1:1 ion association model (purple dotted-dashed line), the cationic (grey line) and anionic (blue dashed line) sandwich association model, and the mixed sandwich association model (brown short-dashed line).

2.1.6 Characterization of Additive PPh₄BF₄ (**6**)

The “wide range” measurement for **3a** were performed with the total ion concentration in solution being kept constant by the addition of an additive, that remained structurally as close as possible to catalyst **3a**. Therefore, tetraphenylphosphonium tetrafluoroborate (PPh₄BF₄, **6**) was synthesized by salt metathesis from tetraphenylphosphonium bromide with sodium tetrafluoroborate in water. After extraction with DCM, the final product was obtained by precipitation from DCM with toluene with 88% yield.

Scheme 2.7: [Scheme S7]. Synthesis of tetraphenylphosphonium tetrafluoroborate PPh₄BF₄ (**6**).

Additive **6** was examined with conductivity measurements in MeCN and DCM. The results are shown in Figure 2.15. In both solvents, additive **6** showed a slightly higher conductivity than ion pair catalyst **3a**.

Figure 2.15: [Figure S21]. a) Concentration-dependent conductivity profile for additive **6** and catalyst **3a** in MeCN at 20 °C, b) Concentration-dependent conductivity profile for additive **6** and catalyst **3a** in DCM at 20 °C.

The conductivity profile of **6** was used to determine the respective association constants K (Table 2.17) which were obtained by employing eq. 2.6, the double ion pairing model as well as the sandwich association model 3a (see Chapter 2.1.4.4). For the determination of the sandwich association constant K_{CAC} , it was crucial to assess the contribution of the single ion towards the molar conductivity Λ_m , gained by linear extrapolation of the initial three data points.

Table 2.17: [Table S21]. Association constants K_{IP} in different solvents according to eq. 2.6, double K_{IP} , and K_{CAC} according to model 3a of pyridinamide ion pairs **3a**, **4a** and additive **6** and at 20 °C.

Ion Pair	$K_{\text{IP}} \text{ (M}^{-1}\text{)}$		$K_{\text{IP}} \text{ (M}^{-2}\text{)}$	$K_{\text{CAC}} \text{ (M}^{-2}\text{)}$
	MeCN [45.6] ^a	DCM [40.7] ^a	DCM [40.7] ^a	DCM [40.7] ^a
3a	34.6	828	6.86×10^5	6.38×10^6
4a	42.9	938	8.79×10^5	6.50×10^6
6	45.6	1004	1.01×10^6	7.05×10^6

[a] $E_{\text{T}}(30)$ [kcal mol⁻¹] solvent polarity parameters taken from Reichardt^[5].

Next, additive **6** was employed in the wide range measurement of **3a** in DCM. Except for the addition of **6** as a second stock solution, the method was remained unchanged. In a first step, the overall ionic concentration I was set to be 1.0 mM for all eleven data point of this measurement (Figure S9, turquoise diamonds). Now, instead of the previously measured non-linear correlation between $[\text{IP}]_{\text{tot}}$ and k_{obs} , a linear correlation was observed.

Figure 2.16: [Figure S22]. Plot of k_{obs} vs. concentration of catalysts **3a** over a concentration range from 0.01–1.0 mM in DCM at 20°C (blue diamonds), and with the additive PPh_4BF_4 (**6**) with a total ionic strength $I = 1.0 \text{ mM}$ (turquoise points).

There are two ways to interpret this data: A) The association equilibrium of **3a** was pushed to the product side by the addition of additive **6** while the solvent polarity remains unchanged. B) The solvent polarity was changed by the addition of additive **6**, indicating that the second-order reaction rate k_2 and the association constant K_{IP} are depending on the concentration of salt **6**. Which one of the assumptions holds true, was checked with DOSY measurements as well as $E_{\text{T}}(30)$ value measurements of DCM at different salt concentrations.

First, the solvent polarity was determined by using the Reichardt's dye betaine $E_{\text{T}}(30)$. The $E_{\text{T}}(30)$ dye was dissolved in dry DCM and mixed with stock solutions of the respective salt. The UV/Vis spectrum was measured. The $E_{\text{T}}(30)$ values of the mixture were calculated according to eq. 2.12 in which h is the Planck's constant, c is the speed of light, and N_{A} is the Avogadro's constant.

$$E_{\text{T}} = \frac{hcN_{\text{A}}}{\lambda_{\text{max}}} = \frac{28951}{\lambda_{\text{max}}} \quad (2.12)$$

A gradual increase in the $E_{\text{T}}(30)$ values was observed for DCM with increasing concentrations of **3a** and **6**, respectively. The results are listed in Table 2.18.

Table 2.18: [Table S22]. Structure of Betaine E_T(30) with a list of measured λ_{max} of Betaine respective with ion pair **3a** and additive **6** in DCM.

Salt (mM)	λ_{max} (nm) with 3a	E _T (30) (kcal mol ⁻¹)	λ_{max} (nm) with 6	E _T (30) (kcal mol ⁻¹)
0.1	698	41.0	698	41.0
0.5	698	41.0	698	41.0
1.0	697	41.0	700	40.9
2.0	696	41.1	700	40.9
3.0	698	41.1	699	40.9
4.0	694	41.2	694	41.2
5.0	694	41.2	–	–
6.0	696	41.1	–	–

As a second measure, DOSY measurements were utilized to determine the association state at an overall salt concentration of 1.0 mM with an increasing portion of ion pair **3a** in solution (Table 2.19).

Table 2.19: [Table S13]. Viscosity corrected hydrodynamic radii r_H and resulting volumes of ion pair **3a** while fixing the overall ion concentrations at 1.0 mM. PPh₄BF₄ was chosen as additive (Add) to keep the ion concentration at 1.0 mM. The ratio of 3a/Add is given in percentage. TMS was used as viscosity reference for the experimental self-diffusion coefficients D_i to allow for a comparison of hydrodynamic radii r_H and resulting volumes V_A . SW = 22 Hz, O1P = 10.0 ppm, gradient strength 5-95% linear. Samples were measured at room temperature.

	[3a] (mM)	Radius (Å)	Volume (Å ³)
Cation	1.0	5.51	642 ^[a]
Anion	1.0	5.15	505 ^[a]
	0.2	5.32	631
Cation	0.5	5.44	673
	0.8	5.39	656
	0.2	4.98	519
Anion	0.5	5.03	528
	0.8	5.03	535

[a] averaged value based on data from ref [2].

To summarize, the measured volumes of the anion at an overall salt concentration of 1.0 mM were located in the same region as the anion volume of pure **3a** at 1.0 mM. By keeping a constant salt concentration throughout the measurement through the addition of additive **6**, the association of the respective pyridinamide ion pair can be “frozen” at a certain association state.

2.1.7 Nucleophilicity Data

The rates of the reactions of ion pair catalysts **3a** and **4a** as well as of **TCAP** with the reference electrophiles were measured photometrically on a stopped-flow spectrophotometer. The temperature was controlled with a circulating bath cryostat. The reactions were carried out under pseudo-first-order conditions (ion pair = nucleophile, excess compound) and monitored at the absorption maximum of benzhydrylium ion in the respective solvent as described previously by the H. Mayr group.^[17] First-order rate constants k_{obs} (s^{-1}) were derived by fitting the absorbance decay according to the mono-exponential function $A_t = A_0 \exp(-k_{\text{obs}} t) + C$ (see Figure 2.17).

Figure 2.17: [Figure S23]. Absorbance decay of benzhydrylium salt **5a** reacting with the nucleophile TCAP (**2**) in DCM at 20°C, fitted by a mono-exponential decay function resulting in $k_{\text{obs}} = 1.19 \text{ s}^{-1}$.

Second-order rate constants k_2 ($\text{L mol}^{-1} \text{ s}^{-1}$) were obtained from the slope of the linear plots of k_{obs} (s^{-1}) vs $[\text{Nu}]$ since $k_{\text{obs}} = k_2[\text{Nu}]$. The subsequent characterization is based on the Mayr-Patz eq. (2.13) where the second-order rate constants ($\log k_2^{20^\circ\text{C}}$) for the reaction of the nucleophile with the electrophile is expressed as a function of the nucleophilicity parameter N , the nucleophile-associated sensitivity parameter s_N , and the electrophilicity parameter E . Both, N and s_N parameter are solvent dependent.^[17–19]

$$\log k_2^{20^\circ\text{C}} = s_N(N + E) \quad (2.13)$$

2.1.7.1 Mayr's benzhydrylium method – Results in MeCN and DCM at $c = 0.01$ - 0.03 mM

Mayr's benzhydrylium method is applicable for dissociated ion pairs, therefore, the data gathered in MeCN can be easily analyzed according to the standard procedure. Measurements done in DCM require more consideration for the analysis since ion association affects the measurements. Salt **3a** will be used as reference system to discuss any new model and data analysis procedures. To circumvent the effects of association, initial measurements in DCM were done between $0.01 - 0.03 \text{ mM}$ where salt **3a** is assumed to be fully dissociated into the free anion **3** and cation **a**, with anion **3** being the only nucleophilic species in solution. The total amount of the fully dissociated **3a** in solution is annotated as $[\mathbf{3}]_{\text{tot}}$, meaning that the weighed amount of **3a** = amount of free anion **3** in solution. Kinetic data obtained using Mayr's benzhydrylium method are summarized in Table 2.20.

Table 2.20: [Table S24]. Second-order rate constants for the reactions of **3a** with (lil)₂CHBF₄ (**5a**), (jul)₂CHBF₄ (**5b**), and (ind)₂CHBF₄ (**5c**) determined in the concentration range $[3]_{\text{tot}} = 0.01 - 0.03$ mM in DCM (blue diamonds) and MeCN (orange dots) at 20 °C and the corresponding *N*- and *s_N*-parameters.

Solvent	Nucleophile	k_2 (M ⁻¹ s ⁻¹)			<i>N/s_N</i>
		5a	5b	5c	
MeCN	[3]_{tot}	7.16×10^3	1.53×10^4	4.13×10^4	16.38/0.60
DCM	[3]_{tot}	1.82×10^6	4.23×10^6	1.98×10^7	17.75/0.81

In MeCN, the correlation between k_{obs} for **3** + **5** reactions and the total concentration of **3a** in solution are linear (see Table 2.20). This is due to the sufficient polarity of MeCN to dissociate salts into the corresponding free anions and cations. However, this stabilizing influence also results in a considerably lower nucleophilicity of **3** when compared to its measurement in DCM. In DCM, the nucleophilic anion **3** experiences less solvation, rendering it more readily available to react with electrophiles **5**. Consequently, the second-order rate constant k_2 for **3** + **5** reactions are approx. three orders of magnitude higher in DCM than in MeCN.

This analysis was made under the assumption that **3a** is mainly, if not fully, dissociated in DCM at concentrations below 0.03 mM. A way to check this assumption is using numerical simulations according to the cationic sandwich association model (see Chapter 2.1.4.4) to determine how much free anion **3** was present in solution. We know the total salt concentration of **3a** at each data point, so this concentration was given as the initial concentration of the anion and cation concentration in COPASI. In the section “reaction”, the rate constant k_1 was set to the value of the cationic sandwich association constant K_{CAC} , while the rate constant k_2 was fixed to 1. Then, the function “Steady State” was used to get the concentration for each species at the given concentration. This process was repeated for each salt concentration of **3a**. Now the first-order rate constant k_{obs} were plotted against the anion concentration **[3]** to get the second-order rate constant k_2 for the nucleophilic anion **3** in solution. This led to the results listed in Table 2.21.

Table 2.21: [Table S25]. Second-order rate constants for the reactions of **3a** in the full dissociation model (where **[3]** = **[3a]_{tot}**, blue diamonds) and the sandwich association model (purple dots) with benzhydrylium electrophile salts (lil)₂CHBF₄ (**5a**), (jul)₂CHBF₄ (**5b**), and (ind)₂CHBF₄ (**5c**) between 0.01 – 0.03 mM in DCM at 20 °C and the corresponding *N*- and *s_N*-parameters.

Conditions	Superscript	Nucleophile	<i>k₂</i> (M ⁻¹ s ⁻¹)			<i>N/s_N</i>
			5a	5b	5c	
<i>I</i> = 0.01-0.03 mM	LC	[3]_{tot}	1.84 × 10 ⁶ [a]	4.23 × 10 ⁶	1.98 × 10 ⁷	17.78/0.81
Sandwich model	LC,sw	[3]	1.84 × 10 ⁶	4.28 × 10 ⁶	2.00 × 10 ⁷	17.78/0.81

[a] the reaction of **3a** with **5a** was measured twice, resulting in $k_2^{\text{LC}} = 1.82 \times 10^6 \text{ M}^{-1} \text{ s}^{-1}$ (*I* = 0.01-0.03 mM) and $k_2^{\text{LC}} = 1.86 \times 10^6 \text{ M}^{-1} \text{ s}^{-1}$ (*I* = 0.01-0.04 mM, initial three data points of wide range measurement) giving an average $k_2^{\text{LC}} = 1.84 \times 10^6 \text{ M}^{-1} \text{ s}^{-1}$.

At low salt concentrations, where **[3a]** = 0.01 – 0.03 mM in DCM (superscript LC), the second-order rate constant k_2^{LC} were obtained by assuming that the total salt concentration **[3]_{tot}** = the free anion concentration **[3]**. Additionally, second-order rate constant $k_2^{\text{LC,sw}}$ were determined by using the free anion concentration **[3]** obtained with numerical simulations. The resulting rate constant k_2^{LC} and $k_2^{\text{LC,sw}}$ revealed only minor differences and identical *N* and *s_N* parameters. We conclude that at low concentrations salt **3a** is mainly dissociated, and the assumption of **[3]** = **[3a]_{tot}** is valid.

By applying the cationic sandwich model (model 3a) to the kinetic data of the wide range measurement performed in DCM over a wider concentration range (0.01 – 1.0 mM), the concentration of free anion **3** was determined and plotted against the pseudo-first order rate constant k_{obs} . The resulting correlation between k_{obs} and anion **3** concentration was expected to be linear and following the black dashed trendline (see Figure 2.18).

Figure 2.18: [Figure S24]. Plot of k_{obs} vs. concentration of catalysts **3a** over a concentration range from 0.01–1.0 mM in DCM at 20°C (blue diamonds), and vs. concentration of anion **3** over a concentration range from 0.01–1.0 mM in DCM at 20°C (grey dots).

Instead, the result was a steeper, but still non-linear correlation indicating that the association of **3a** is not the only process that influences the kinetic measurements. Assuming that the change in overall ionic strength when going from 0.01 mM to 1.0 mM salt concentrations might be responsible for this non-linear behavior, rate measurements were repeated in the presence of $\text{PPh}_4^+\text{BF}_4^-$ (**6**). The additive was added to maintain a constant ionic strength of 1.0 mM over all pyridinamide salt concentrations. The choice of salt **6** combined cation **a** of **3a** with the tetrafluoro borate anion (BF_4^-), which is the counter-anion of the benzhydrylium electrophile salts. Addition of **6** increased the concentration of phosphonium cation **a** and, thus the concentration of sandwich cation **a3a**, resulting in a linear correlation of the first-order rate constant k_{obs} and the nucleophile concentration (see Figure 2.19, turquoise points).

Figure 2.19: [Figure S25]. Plot of k_{obs} vs. concentration of catalysts **3a** over a concentration range from 0.01–1.0 mM in DCM at 20°C (blue diamonds), and with additive PPh_4BF_4 (**6**) with a $[\text{IP}]_{\text{tot}} = 1.0$ mM (turquoise points).

2.1.7.2 Cationic Sandwich Association Extension

The measurements performed with the addition of additive **6** can be analyzed in multiple ways. The first way would be to assume that the amount of weighted salt **3a** equals the amount of nucleophile in solution. Here, we would simply use the standard Mayr's benzhydrylium method to obtain the second-order rate constant k_2 and subsequently gain the N parameter and s_N parameter (see Table 2.22).

From the combination of conductivity and DOSY measurements, we know that the salt **3a** associates into triple ionic adducts, so-called sandwich cations. Therefore, the weighted amount of salt **3a** is most likely not equivalent to the concentration of the reactive nucleophile in solution. We assume here, that the sandwich complex does not react as a nucleophile, but rather only the free anion **3**.

Again, we use the earlier established association model 3a for the cationic sandwich association with $K_{CAC} = k_1/k_2 = 6.38 \times 10^6 \text{ M}^{-2}$. Except now, we have to add one more reaction to the biochemical model for the sandwich association of **3a** in COPASI to incorporate the influence of additive **6** in the numerical simulations. The additive can either associate according to the 1:1 model or according to the sandwich model (see eq. 2.14)

Depending on the chosen association type, either eq. 2.14a or eq. 2.14b was added to the biochemical model as "additive association" with **C** = PPh_4^+ , **B** = BF_4^- , and **CB** = PPh_4BF_4 (**6**) or the sandwich adduct **CBC** = $\text{PPh}_4\text{BF}_4\text{PPh}_4$.

		CBC		mol/l

The additive association constant was determined using the same procedure as for the sandwich association constant K_{CAC} of compound **3a** and was defined as either $K_{IP}(\mathbf{6}) = k_1/k_2 = 1.01 \times 10^6 \text{ M}^{-2}$ or $K_{CAC}(\mathbf{6}) = k_1/k_2 = 7.05 \times 10^6 \text{ M}^{-2}$.

Next, in the section “Species” the individual concentration for all compounds were added. As a starting point for this model, we assume that both salts are completely dissociated. Therefore, $[A]$ = concentration of salt **3a**, $[C]$ = concentration of salt **3a** + concentration of additive **6**, and $[B]$ = concentration of additive **6** + concentration of the respective benzhydrylium salt **6**.

The function “Steady State” was used to obtain the concentrations for each species for the given association constants. This process was repeated for each salt concentration of **3a**. Subsequently, the concentration of the single anion **3** can be plotted against k_{obs} to get the second-order rate constant k_2 for the reactive nucleophilic anion **3** in solution. All three resulting sets of reaction rates k_{obs} are depicted in Figure 2.20.

Figure 2.20: [Figure S26]. Plot of k_{obs} vs. concentration of catalysts **3a** with additive **6** (turquoise diamonds), concentration of anion **3** obtained with model “HC,IP” (green dots) and concentration of anion **3** obtained with model “HC,sw” (grey dots) over a concentration range from 0.01–1.0 mM in DCM at 20°C with constant ionic strength $I = 1.0 \text{ mM}$.

To distinguish the second-order rate constants k_2 obtained with all model variations, the following superscripts were introduced: “LC” = $[3]_{tot}$ with I = variable (blue); “LC,sw” = $[3]$ with I = variable (purple);

“HC” = $[3]_{\text{tot}}$ with $I = 1.0$ mM (turquoise); “HC,IP” = $[3]$ with $I = 1.0$ mM (green); “HC,sw” = $[3]$ with $I = 1.0$ mM (grey, see Table 2.22).

Table 2.22: [Table S26]. Second-order rate constants obtained with all five possible analysis methods for salt **3a** with benzhydrylium electrophiles salts (lil)₂CHBF₄ (**5a**), (jul)₂CHBF₄ (**5b**), and (ind)₂CHBF₄ (**5c**) between 0.01 – 0.03 mM in DCM at 20 °C and the corresponding N - and s_N -parameters.

Conditions	Superscript	Nucleophile	k_2 (M ⁻¹ s ⁻¹)			N/s_N
			5a	5b	5c	
$I = 0.01\text{--}0.03$ mM	LC	$[3]_{\text{tot}}$	1.84×10^6 ^[a]	4.23×10^6	1.98×10^7	17.78/0.81
Sandwich model	LC,sw	3	1.84×10^6	4.28×10^6	2.00×10^7	17.78/0.81
$I = 1.0$ mM	HC	$[3]_{\text{tot}}$	3.58×10^5	8.28×10^5	3.23×10^6	17.40/0.75
6 → 1:1 association	HC,IP	3	7.23×10^5	1.67×10^6	7.17×10^6	18.04/0.73
6 → sw associaton	HC,sw	3	5.43×10^5	1.25×10^6	4.87×10^6	17.61/0.75

[a] the reaction of **3a** with **5a** was measured twice, resulting in $k_2^{\text{LC}} = 1.82 \times 10^6$ M⁻¹ s⁻¹ ($I = 0.01\text{--}0.03$ mM) and $k_2^{\text{LC}} = 1.86 \times 10^6$ M⁻¹ s⁻¹ ($I = 0.01\text{--}0.04$ mM, initial three data points of wide range measurement) giving an average $k_2^{\text{LC}} = 1.84 \times 10^6$ M⁻¹ s⁻¹.

To summarize, at low concentrations between 0.01 – 0.03 mM while the ionic strength I in solution is variable, the second-order rates k_2^{LC} and $k_2^{\text{LC,sw}}$ are almost identical, which results in identical N and s_N parameters. With the addition of additive **6**, the main issue for the determination of the nucleophilicity of anion **3** at higher concentrations being the ongoing association of **3a** was circumvented. Depending on the chosen model for the subsequent analysis, the resulting second-order rate constants k_2 differ from one another. So was $k_2^{\text{HC,IP}}$ 1.3 times faster than $k_2^{\text{HC,sw}}$, while both were 2.0 and 1.5 times faster than k_2^{HC} , respectively. Overall, the nucleophile-specific sensitivity s_N fell within a narrow window (0.81 vs. 0.73), implying that the relative reactivity of anion **3** was not significantly influenced by the addition of additive **6**.

2.1.7.3 Mixed Sandwich Association Extension

Previously, we applied the cationic sandwich model (model 3a) to determine the concentration of free nucleophilic anion **3** in kinetic measurements performed in DCM at higher concentrations, expecting a linear correlation between k_{obs} and $[3]$ (grey dots, see Figure 2.21). Instead, a steeper but still non-linear correlation was observed. By applying the mixed sandwich association model (model 4) to the same kinetic data, the resulting correlation between k_{obs} and $[3]$ was still non-linear, but closer to the ideal theoretical correlation than the correlation based on model 3a (brown dots, see Figure 2.21).

Figure 2.21: [Figure S27]. Plot of k_{obs} vs. concentration of catalysts **3a** over a concentration range from 0.01–1.0 mM in DCM at 20°C (blue diamonds), vs. concentration of anion **3** over a concentration range from 0.01–1.0 mM in DCM at 20°C based on the sandwich association model **3a** (grey dots), and vs. concentration of anion **3** over a concentration range from 0.01–1.0 mM in DCM at 20°C based on the mixed sandwich association model **4** (brown dots).

The mixed model came closer to the theoretical ideal case of the predicted linear correlation between k_{obs} and **[3]**, indicating a step forward in the development of a comprehensive association model for pyridinamide ion pairs as **3a**.

Next, the mixed sandwich association model (model **4**) was used to analyze the ionic strength-controlled kinetic data. Therefore, model **4** was extended by adding eq. 2.14b to account for the additive association whilst taking both cationic and anionic sandwich association into account in analyzing the nucleophilicity data (see Scheme 2.8). Moving forward, it was assumed that additive **6** associates in according to the cationic sandwich association model.

Scheme 2.8: [Scheme S8]. Mixed model with additive association extension for the analysis of nucleophilicity data.

For numerical simulations, the same procedure was followed as described earlier for the cationic sandwich association extension. For ion pair **3a**, the following association constants $K_{\text{CAC}}(\mathbf{3a}) = k_1/k_2 = 2.81 \times 10^6 \text{ M}^{-2}$, and $K_{\text{ACA}}(\mathbf{3a}) = k_1/k_2 = 1.34 \times 10^6 \text{ M}^{-2}$, were applied with $K_{\text{CAC}}(\mathbf{6}) = 7.05 \times 10^6 \text{ M}^{-2}$ still being the same value as before for measurements done with constant ionic strength $I = 1.0 \text{ mM}$.

Numerical simulation according to the mixed sandwich association extension gave the concentration of the free anion **3** as well as the concentration of the sandwich anion **3a3**, which could potentially act as another nucleophile. To discuss the different options, we look at the correlation between k_{obs} and the respective nucleophile concentration (see Figure 2.22).

Figure 2.22: [Figure S28]. Plot of k_{obs} vs. concentration of catalysts **3a** over a concentration range from 0.01–1.0 mM in DCM at 20°C (blue diamonds), k_{obs} vs. anion **3** over a concentration range from 0.01–1.0 mM in DCM at 20°C based on the sandwich association model 3a (grey dots), k_{obs} vs. anion **3** + anion sandwich **3a3** over a concentration range from 0.01–1.0 mM in DCM at 20°C based on the mixed sandwich association model 4 (yellow dots), k_{obs} vs. anion **3** over a concentration range from 0.01–1.0 mM in DCM at 20°C based on the mixed sandwich association model 4 (brown dots), and k_{obs} vs. anion sandwich **3a3** over a concentration range from 0.01–1.0 mM in DCM at 20°C based on the mixed sandwich association model 4 (blue dots).

The anionic sandwich complex **3a3** is unlikely to be the more reactive nucleophile due to its reduced reactivity caused by complexation. Simultaneously, its concentration was far too low to plausibly be the main reacting nucleophile. In the best-case scenario both the free anion **3** and the anion sandwich **3a3** react equally as nucleophiles (yellow correlation). This would give a correlation that is virtually overlapping with the correlation obtained with numerical simulation according to the cationic sandwich association model 3a (grey dots). As already established, the correlation for k_{obs} vs. **3** obtained by applying the mixed sandwich association model 4 (brown dots) was closest to the predicted ideal linear correlation. Moving forward, we will focus on two possible nucleophiles in solution being either the free anion **3** or the combination of **3** + **3a3**.

Looking at the second-order rate constant obtained by plotting k_{obs} against **3** based on model 3a or model 4 and k_{obs} against **3** + **3a3**, it can be determined that the deviations are clearly visible, but all are in a reasonable window (see Figure 2.23).

Figure 2.23: [Figure S29]. Plot of k_{obs} vs. concentration of catalysts **3a** with additive **6** (turquoise diamonds), concentration of anion $[3] + [3a3]$ obtained with model 4 ("HC,mix", yellow dots), concentration of anion $[3]$ obtained with model 4 ("HC,mix", brown dots), and concentration of anion $[3]$ obtained with model ("HC,sw", grey dots) over a concentration range from 0.01–1.0 mM in DCM at 20°C with constant ionic strength $I = 1.0$ mM.

The new superscript "HC,mix" = $[3]_{\text{tot}}$ with $I = 1.0$ mM (brown) was introduced to distinguish the second-order rate constants k_2 and the resulting N - and s_N -parameters based on the derived mixed sandwich association extension. While the differences in the second-order rate constant are still noticeable, the resulting N - and s_N -parameter are almost overlapping. Therefore, while the analysis of the kinetic data with due regard to the effects of ion association is relevant to obtain a reliable second-order rate constant, for practicability, it is within a justifiable window of deviation to use the overall ion pair concentration $[3]_{\text{tot}}$ and follow the established Mayr method for the data evaluation of the ionic strength-controlled measurements. In Table 2.23, all second-order rate constants k_2 and the resulting N - and s_N -parameter are summarized for all seven executed ways of evaluation for pyridinamide ion pair **3a**.

Table 2.23: [Table S27]. Second-order rate constants obtained with all seven possible analysis methods for salt **3a** with benzhydrylium electrophiles salts $(\text{lii})_2\text{CHBF}_4$ (**5a**), $(\text{jul})_2\text{CHBF}_4$ (**5b**), and $(\text{ind})_2\text{CHBF}_4$ (**5c**) between 0.01 – 0.03 mM in DCM at 20 °C and the corresponding N - and s_N -parameters.

6 → sw associaton	HC,mix	[3]+[3a3]	4.85×10^5	1.12×10^6	4.26×10^6	17.69/0.74
6 → sw associaton	HC,mix	3	5.42×10^5	1.25×10^6	4.64×10^6	17.88/0.73

[a] the reaction of **3a** with **5a** was measured twice, resulting in $k_2^{\text{LC}} = 1.82 \times 10^6 \text{ M}^{-1} \text{ s}^{-1}$ ($I = 0.01\text{-}0.03$ mM) and $k_2^{\text{LC}} = 1.86 \times 10^6 \text{ M}^{-1} \text{ s}^{-1}$ ($I = 0.01\text{-}0.04$ mM, initial three data points of wide range measurement) giving an average $k_2^{\text{LC}} = 1.84 \times 10^6 \text{ M}^{-1} \text{ s}^{-1}$.

In future applications of the mixed sandwich association model, the free anion **3** is treated as the only active nucleophile in solution. The sandwich anion will not be considered in the analysis.

2.1.7.5 Kinetic Data of wide range measurements

The herein called wide range measurements employ the same principle as the benzhydrylium kinetics except for covering a much larger concentration range (1×10^{-5} to 4×10^{-3} M). The aim of these measurement was to illustrate the influence of ion pair association on the first-order reaction rate k_{obs} (s^{-1}) with increasing concentration. The hereby potentially obtained second order rate constants k_2 ($\text{M}^{-1} \text{s}^{-1}$) are not included in the N and s_N parameter determination. The benzhydrylium salt $(\text{lil})_2\text{CH}^+\text{BF}_4^-$ (**5a**) was used as electrophile at $\lambda = 640$ nm.

2.1.7.5.1 Wide range data at 20 °C

Tetraphenylphosphonium pyridin-4-yl((trifluoromethyl)sulfonyl)amide (**3a**)

Tetraphenylphosphonium tetrafluoroborate (**6**)

2.1.10 Computational Study

2.1.10.1. General information

All substrate structures were optimized with the B3LYP-D3 hybrid functional^[21–23] with the 6-31+G(d) basis set.^[24] Solvent effects for dichloromethane and acetonitrile have been calculated with the SMD continuum solvation model.^[25] This combination has worked well in previous studies of charge-separated intermediates.^[26–29] Frequency and single point calculations were performed at the same level of theory. Thermochemical correction to 198.15 K has been applied to all found minima from unscaled vibrational frequencies obtained at the same level of theory. To lessen the impact of low-lying frequencies of large systems on entropy and enthalpy in an unpredictable manner, a free-rotor approximation for entropy as proposed by Grimme^[30] and a quasi-harmonic treatment with a cutoff value of 100 cm⁻¹ using Goodvibes^[31] was applied. Free energies in solution have been corrected to the reference state of 1.0 mol L⁻¹ at 298.15 K by adding 7.925 kJ mol⁻¹ to the free energies ($G_{298,qh,corr}$). All reported calculations were done with Gaussian 16, Revision A.03^[32] and B.01^[33].

The conformational search was performed with Maestro^[34]. For ion pair systems, a set of 150 starting points was obtained by using the stochastic kick procedure invented by Saunders^[35] and further developed by Sakic^[36]. At a time, a set of 50 starting points was generated by a combination of the best and the second-best conformer of the prior separately optimized anion and cation. The last 50 starting points were obtained from the combination of the best anion conformer with the third best cation conformer. The following kick settings were used: Distance parameter: 3 Å, Minimal Distance 1.5 Å, Number of Fragments: 1, Number of Files: 50.

Starting points for the conformers of the ion pair systems were obtained from Julian Helberg. Conformers for the new systems with tetraphenyl phosphonium as cation (**3a**) were obtained by manual modification of the corresponding triphenyl methyl phosphonium containing systems, initially calculated by Helberg^[37], whereby the methyl group was replaced by a phenyl group.

Starting points for the conformers of the sandwich cation and sandwich anion were obtained by sorting the optimized structures of the respective ion pair according to the total energy. The best six conformers were chosen and in combination with the best cation **a** conformer the stochastic kick procedure invented by Saunders^[35] and further developed by Sakic^[36] was applied to generate 60 new substrate structures in total. The following kick settings were used: Distance parameter: 3 Å, Minimal Distance 1.5 Å, Number of Fragments: 1, Number of Files: 10.

The goal in calculating the respective sandwich conformers was to obtain the volumes based on the van der Waals cavities employed in the SMD continuum solvation model at the SMD(DCM)/B3LYP-D3/6-31+G(d) level of theory for the calculation of the volumes of ions based on the simulated concentrations in each respective conductivity model to compare the DOSY results with the results of the numerical simulations. Due to the heavy nature of the calculated systems (between 81 – 119 atoms) the less costly r²SCAN-3c developed by Grimme^[38] with Orca 5.0.3^[39] was used for pre-optimizations, followed by single point calculations at the SMD(DCM)/B3LYP-D3/6-31+G(d) level of theory with Gaussian 16, Revision C.01^[40].

2.1.10.2 System **3a** – computational information**Figure 2.24:** [Figure S30]. Ion pair formation of **3a** and the single ions.

The Boltzmann-averaged free reaction energy of the ion pairing of **3a** amounts to $\Delta G_{\text{qh},298,\text{corr}} = +1.6 \text{ kJ mol}^{-1}$ in DCM solution. Focusing only on the best conformers of the reactants and product the free reaction energy of the ion pairing of **3a** changes to $\Delta G_{\text{qh},298,\text{corr}} = +1.1 \text{ kJ mol}^{-1}$ in DCM solution. This result is mainly due to solvation effects since the gas phase free energy of the ion pairing amounts to $\Delta G_{\text{qh},298} = -218.5 \text{ kJ mol}^{-1}$. In addition, we note that the contribution of the D3-dispersion correction amounts to $\Delta E_{\text{disp}} = -57.7 \text{ kJ mol}^{-1}$ for the free energy in the DCM solution and in the gas phase. The blue marked cells show the Boltzmann-averaged values.

According to $\Delta G_{\text{qh},298,\text{corr}} = -RT \ln K$ and assuming $R = 8.314 \text{ J K}^{-1} \text{ mol}^{-1}$ and $T = 298.15 \text{ K}$, the respective equilibrium constant amounts to $K(\mathbf{3a}, \text{DCM}) = 0.63$ for the best conformer of **3a** and to $K(\mathbf{3a}, \text{DCM}) = 0.52$ for the Boltzmann-averaged free reaction energy. In this case the equilibrium constant K corresponds to the concentration of the reactants and products in the following way: $K = [\mathbf{3a}]/[\mathbf{3}] [\mathbf{a_PPh4}] = [\mathbf{3a}]/[\mathbf{3}]^2$.

Table 2.26: [Table S30]. Energies for all systems shown in Figure 2.24.

2.1.10.3 System **4a** – computational information

**Figure 2.26:** [Figure S32]. Ion pair formation of **4a** and the single ions.

The Boltzmann-averaged free reaction energy of the ion pairing of **4a** amounts to $\Delta G_{\text{qh},298,\text{corr}} = -4.3 \text{ kJ mol}^{-1}$ in DCM solution. Focusing only on the best conformers of the reactants and product the free reaction energy of the ion pairing of **4a** changes to $\Delta G_{\text{qh},298,\text{corr}} = -6.7 \text{ kJ mol}^{-1}$ in DCM solution. This result is mainly due to solvation effects since the gas phase free energy of the ion pairing amounts to $\Delta G_{\text{qh},298} = -227.3 \text{ kJ mol}^{-1}$. In addition, we note that the contribution of the D3-

dispersion correction amounts to $\Delta E_{\text{disp}} = +136.6 \text{ kJ mol}^{-1}$ for the free energy in the DCM solution and in the gas phase. The blue marked cells show the Boltzmann-averaged values.

According to $\Delta G_{\text{qh},298,\text{corr}} = -RT \ln K$ and assuming $R = 8.314 \text{ J K}^{-1} \text{ mol}^{-1}$ and $T = 298.15 \text{ K}$, the respective equilibrium constant amounts to $K(\mathbf{4a}, \text{DCM}) = +15.0$ for the best conformer of **4a** and to $K(\mathbf{4a}, \text{DCM}) = +5.6$ for the Boltzmann-averaged free reaction energy. In this case the equilibrium constant K corresponds to the concentration of the reactants and products in the following way: $K = [\mathbf{4a}]/[\mathbf{4}] [\mathbf{a_PPh4}] = [\mathbf{4a}]/[\mathbf{4}]^2$.

Table 2.31: [Table S35]. Energies for all systems shown in Figure 2.26.

Chapter 3. Pyridinamide Ion Pairs – Design Principles for Super-Nucleophiles in Apolar Organic Solvents

Veronika Burger, Maximilian Franta, AnnMarie C. O'Donoghue*, Armin R. Ofial*, Ruth M. Gschwind* and Hendrik Zipse*

J. Org. Chem., **2024**, in revision (Manuscript ID jo-2024-02668y).

Author contributions: Veronika Burger (V.B.) and Hendrik Zipse (H.Z.) conceived the study. All experimental studies were performed by V.B. with exception of DOSY NMR measurements, which were performed by Maximilian Franta (M.F.). AnnMarie C. O'Donoghue (A.C.O) supervised the design and execution of pK_a measurements, which were performed at Durham University. The manuscript was jointly written by V.B., Ruth M. Gschwind (R.M.G.), Armin R. Ofial (A.R.O.) and H.Z. The supporting information was prepared by V.B. and M.F.

Additional information: The here displayed supporting information is an altered and shorted version of the submitted SI. The DOSY results are used for the explanation of findings, but no technical details are discussed in this thesis. These can be found in the original file. For comparison of this thesis and the original SI file, the numbering includes the original item number as shown below.

Pyridinamide Ion Pairs – Design Principles for Super-Nucleophiles in Apolar Organic Solvents

KEYWORDS: conductivity, DOSY, asymmetric association, catalyst design, nucleophilicity, kinetics, catalysis

ABSTRACT: A comprehensive analytical protocol combining conductivity, diffusion-ordered NMR (DOSY), and photometric kinetic measurements is employed to analyze the nucleophilic reactivity of pyridinamide ion pairs in low polarity organic solvents. The association patterns of these systems are found to strongly depend on cation size, with larger cations favoring the formation of cationic triple ion sandwich complexes together with free and highly nucleophilic anions. Kinetic studies using the ionic strength-controlled benzhydrylium method demonstrate that pyridinamide ions exhibit significantly higher nucleophilicities as compared to established organocatalysts, particularly in low polarity solvents. Nucleophilicities are furthermore found to correlate well with Brønsted basicities measured in water and with Lewis basicities calculated in dichloromethane. Taken together these findings provide quantitative guidelines for the future design of highly active Lewis base catalysts.

INTRODUCTION

In the field of organic synthesis, ion pair catalysis has emerged as a powerful tool that leverages the interaction between charged species to enhance catalytic activity and selectivity to facilitate various chemical transformations.¹⁻⁴ Its application extends from classical phase-transfer (PT) catalysis⁵ to asymmetric synthesis.⁶⁻⁹ Recent studies have shown that ion pair catalysis offers unique opportunities for selectivity control and overcomes challenges where conventional methods may fall short.^{10,11} Pyridinamide ion pairs have recently been introduced as a new class of Lewis base catalysts capable of outperforming established structurally related neutral organocatalysts such as 4-(dimethylamino)pyridine (DMAP, **1**)^{12,13} and the more reactive 9-azajulolidine (TCAP, **2**)¹⁴ in selected benchmark reactions.^{15,16} In contrast to neutral pyridine-based catalysts **1** and **2**, the actual state of the ion pair catalysts shown in Chart 1 depends on a variety of factors such as the solvent polarity, the choice of additives, and the concentration regime used in catalytic processes. For pyridinamide phosphonium salts, such as **3a** and **4a** (Chart 1), we have recently outlined a protocol for quantifying their concentration-dependent speciation and the nucleophilicity of the free anion component towards reference electrophiles of known reactivity in organic solvents of low polarity such as dichloromethane (DCM).¹⁷ Most kinetic studies aiming to quantify the reactivity of anionic nucleophiles rely on highly polar solvents such as water, DMSO, acetonitrile (MeCN), often in combination with additives such as crown ethers to reduce interactions between the cationic counter-ion and the reacting anion.¹⁸ The intrinsic nucleophilicity of a free anion is, however, expected to be higher in organic solvents of low polarity (DCM, THF, toluene) commonly used in organocatalytic transformations. Ion pairs tend

to associate in apolar media in a concentration-dependent manner causing non-linear effects and, thus, complicate systematic kinetic studies.

Chart 1. Structures of neutral organocatalysts DMAP (1**), TCAP (**2**), and the pyridinamide ion pair library.**

Our recently introduced analytical protocol combines conductivity measurements, diffusion-ordered NMR spectroscopy (DOSY) measurements, and photometric kinetic measurements utilizing an ionic strength-controlled benzhydrylium ion methodology and enables us to uniquely link insights into the concentration of ions with their association state and nucleophilicity. For **3a** as a reference system, the results from conductivity and DOSY experiments can best be rationalized by assuming the concentration-dependent formation of the “sandwich”-type cations (**a3a**) and anions (**3a3**) shown in Figure 1, with little interference of the respective 1:1 ion pair (**3a**). Key properties obtained from DOSY experiments in DCM are the

concentration-dependent “effective” cation and anion volumes, whose combination with conductivity data then yields the equilibrium constants for all three aggregates **3a**, **a3a**, and **3a3** shown in Figure 1.

Figure 1. Association types of anion **3** and cation **a** leading to either the 1:1 ion pair **3a**, the sandwich cation **a3a**, or the sandwich anion **3a3** with their respective association constants K_{IP} , K_{CAC} , and K_{ACA} .

While it is, in principle, possible to fit concentration-dependent conductivity and DOSY profiles to only one of the equilibria shown in Figure 1, the best possible fit is obtained when assuming simultaneous formation of both sandwich ion species **a3a** and **3a3**. In practical terms this requires optimization of the mixing parameters α (contribution of sandwich cation **a3a**) and β (contribution of sandwich anion **3a3**) shown in Figure 1. In the following we will refer to this model as the “mixed sandwich ion model” (see SI). The accurate description of concentration profiles for all species was then combined with the ionic strength-controlled benzhydrylium method to determine the nucleophilicity of free pyridinamide anions in DCM and MeCN. Based on the results obtained for pyridinamide ion pairs **3a-d** and **4-6a** we aim to extract key design principles for the synthesis of highly reactive pyridinamide ion pair systems.

RESULTS AND DISCUSSION

Conductivity. Conductivity measurements were performed in DCM for salt concentrations ranging from 0.02 – 1.0 mM. At low electrolyte concentrations and for the case of non-interacting ions, the experimentally determined conductivity κ depends on the specific molar conductivity Λ_m and the ion concentration $[IP]$ as expressed in equation (1).

$$\kappa = \Lambda_m[IP] \quad (1)$$

The conductivity curves for ion pairs composed of anion **3** and cations **a-d** shown in Figure 2A appear to fall into two separate groups. The first of these includes cation **a** (PPh_4^+) and **b** ($PPh_3NPPPh_3^+$) carrying aromatic substituents and displays systematically higher conductivities as compared to the second group with cation **c** (NBu_4^+) and **d** (PBu_4^+) carrying unbranched aliphatic side chains. For simplicity, we will focus our discussion on the cationic sandwich association constants K_{CAC} . Pyridinamide ion pair **3b** shows the weakest degree of association of all ion pairs in DCM with $K_{CAC}(\mathbf{3b}) = 4.65 \times 10^6 \text{ M}^{-2}$, closely followed by **3a** with $K_{CAC}(\mathbf{3a}) = 6.38 \times 10^6 \text{ M}^{-2}$. In contrast, ion pairs **3c** and **3d** show systematically higher values with $K_{CAC}(\mathbf{3c}) = 1.01 \times 10^7 \text{ M}^{-2}$, and $K_{CAC}(\mathbf{3d}) = 1.07 \times 10^7 \text{ M}^{-2}$, respectively, indicating a higher degree of aggregation in DCM.

Variation of the anion substitution pattern leads, in contrast, to only minor variations in the association behavior as is easily

seen from the similar conductivity curves displayed in Figure 2B. In quantitative terms this is reflected in the respective association constants of $K_{CAC}(\mathbf{4a}) = 6.50 \times 10^6 \text{ M}^{-2}$, $K_{CAC}(\mathbf{5a}) = 5.15 \times 10^6 \text{ M}^{-2}$, and $K_{CAC}(\mathbf{6a}) = 6.75 \times 10^6 \text{ M}^{-2}$, all of which are in close proximity to one another and quite similar to that of **3a**. The conductivity measurements thus clearly document that the lowest degree of aggregation (and thus the highest concentration of free ions) will be obtained with the two phosphonium ions **a** and **b** carrying aromatic substituents.

Figure 2. A) Conductivity profiles for **3a**, **3b**, **3c**, and **3d** measured in DCM at 20 °C, B) Conductivity profiles for **3a**, **4a**, **5a**, and **6a** measured in DCM at 20 °C.

DOSY NMR. Since conductivity data alone cannot determine which sandwich association type predominates for a given pyridinamide ion pair, DOSY NMR measurements were performed in DCM- d_2 for concentrations ranging from 0.005 mM to 1.0 mM (see SI, Chapter 4). DOSY measurements at these low concentrations require a 600 MHz spectrometer with a helium cryo probe and measurement times up to 16 h per sample. The DOSY results were compared to calculated volumes of ions and associated complexes of the respective pyridinamide ion pair which are based on the van der Waals cavities employed in the SMD continuum solvation model at the SMD(DCM)/B3LYP-D3/6-31+G(d) level of theory. Recent DOSY measurements of pyridinamide ion pair **3a** and **4a** revealed a prevailing cationic sandwich association for **3a**, and a mainly anionic sandwich association for **4a**.¹⁷ Thereby, the cationic sandwich association is indicated by a higher increase of the hydrodynamic cation volume in comparison to the hydrodynamic anion volume, while the anionic sandwich association displays a distinct crossing point of both ionic volumes when the anion volume surpasses the cation volume of the respective salt in the DOSY measurement. Thus, additional DOSY measurements for the remaining pyridinamide ion pairs were performed to reveal trends in the association behavior.

The concentration dependent DOSY plots of ion pair **3b**, **3c**, and **3d** display a similar curve with cation volumes larger than expected as shown for **3a**. Here the effective cation volume increases more strongly with increasing concentration than the anion volume which is most easily rationalized with predominant formation of cationic sandwich complexes of “**a3a**”-type (see SI for details). In contrast, for ion pairs **4a**, **5a**, and **6a** a crossing point of anion and cation volumes is observed where the anion volume exceeds the cation volume, which is typical for the anionic sandwich complexes of “**a4a**”-type.

Combined analysis of the conductivity and DOSY NMR data points to a predominance of cation sandwich formation for **3a-d** and a predominance of anion sandwich formation for pyridinamide ion pairs **4-6a**. This is quantitatively reflected in the scaling factors α and β collected in Table 1. For ion pair **3b** and **3d** all experimental observables can be rationalized with excellent accuracy with the cation sandwich model alone, that is, $\alpha/\beta = 100/0$.

Table 1. List of pyridinamide ion pairs with their optimized scale factors α and β and the association constants K_{CAC} and K_{ACA} in the mixed sandwich ion model.

IP	α/β	$\alpha \times K_{CAC} [M^{-2}]$	$\beta \times K_{ACA} [M^{-2}]$	RMSE
3a	44/21	2.81×10^6	1.34×10^6	0.43
3b	100/0	4.65×10^6	0.00	0.11
3c	33/23	3.33×10^6	2.32×10^6	0.61
3d	100/0	1.07×10^7	0.00	0.10
4a	12/61	7.80×10^5	3.97×10^6	0.35
5a	11/67	5.67×10^5	3.45×10^6	0.29
6a	16/52	1.08×10^6	3.51×10^6	0.38

In summary, the conductivity data demonstrates the association pattern is more influenced by the choice of cation than anion, whilst the DOSY data reveals a switch from cation sandwich to anion sandwich association when moving from small anion **3** (215 \AA^3) to larger anions such as **4** (285 \AA^3), **5** (266 \AA^3), or **6** (295 \AA^3) when using **a** (362 \AA^3) as the cation component. The size difference between the chosen anion and cation components as listed in Table 2 thus appears to represent a controlling factor for the speciation of ion pairs in organic solvents of low polarity. For the first two entries **3a** and **3b** combining aryl phosphonium cations **a** and **b** with the comparatively small anion **3** we find a predominance of cationic sandwich association. For the combinations of larger anions **4-6** with phosphonium cation **a** the volume difference is significantly smaller ($< 100 \text{ \AA}^3$) and all experiments point to a mixture of cation and anion sandwich association.

Table 2. Analysis of volume difference between anions and cations in pyridinamide ion pairs with aryl substituted cations **a and **b**.**

IP	Cation volume (\AA^3)	Anion volume (\AA^3)	Volume difference ^[a]
3a	362	215	147
3b	559	215	344
4a	362	285	77.0
5a	362	266	96.0
6a	362	295	67.0

[a] Volume difference = cation volume - anion volume.

While the difference between anion and cation volume may not be the only factor that determines the association pattern of pyridinamide ion pairs in organic solvents of low polarity, it is a feature that can be adjusted in a straightforward manner to shift the association equilibria towards the formation of cationic sandwich aggregates (accompanied by an increase of the free anion concentration in solution).

Kinetics. To characterize the nucleophilic reactivity of pyridinamide ion pairs we used the established Mayr benzhydrylium ion method suitable for the quantification of the reactivity of carbon-, nitrogen-, oxygen-, sulfur-, and phosphorus-based nucleophiles in different solvents,^{19,20} including DMAP (**1**) and TCAP (**2**).²¹⁻²³ In order to separate the effects of increasing nucleophile concentration from those of increasing solution ionic strength, we employ the ionic strength-controlled methodology described earlier by adding the non-nucleophilic salts **7a-d** composed of BF_4^- and the respective cation components (see Chart 2) to the reaction mixture to keep the ionic strength (I) constant at $I = 1.0 \text{ mM}$ as the upper concentration limit chosen in conductivity, DOSY, and kinetics measurements.

Chart 2. Structures of non-nucleophilic additives **7a-d employed in ionic-strength controlled benzhydrylium measurements.**

The benzhydrylium ion method involves the photometric monitoring of the reactions of colored benzhydrylium salts, such as **8a-8c** (Table 3) whose electrophilic reactivities are characterized by the solvent-independent parameters E , with nucleophiles used in excess concentration to achieve kinetics under pseudo-first order conditions. The first-order rate constants k_{obs} (s^{-1}) can then be obtained by fitting a mono-exponential decay function to the decreasing absorption of **8** during the reaction with the nucleophile which is assumed to be the anion of the respective ion pair. In MeCN, pyridinamide ion pairs fully dissociate into anion and cation as shown by conductivity measurements. Accordingly, a linear increase of pseudo-first order rate constants k_{obs} with nucleophile concentrations $[A]$ (= anion concentration or total salt concentration) was observed in the kinetics of reactions of pyridinamide ion pairs with **8** [equation (2)].

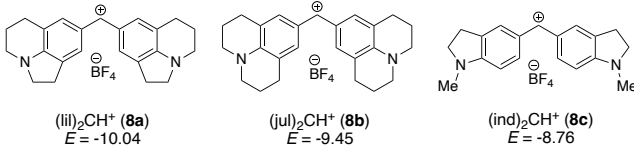

$$k_{\text{obs}} = k_2[A] \quad (2)$$

$$\log k_2 = s_N(N + E) \quad (3)$$

Equation (2) thus yields the second-order rate constants k_2 ($\text{M}^{-1} \text{ s}^{-1}$) for the reactions of pyridinamide ion pair **3a-d, 4-6a** with **8a-8c** in acetonitrile (Table 3). All measured ion pairs containing anion **3** display largely similar bimolecular rate constant k_2 , the spread of individual values amounting to $\pm 10\%$. From all pyridinamide anions studied here, anion **3** is the least reactive species, but still reacts about three times faster with electrophiles **8** than DMAP (**1**) and similarly fast as TCAP (**2**). The highest rate constant k_2 was measured for anion **4** with an electron donating aryl substituent (4-MeO), which is approx. eight times larger than those for analogous reactions of **8** with TCAP (**2**) and closely followed by the rate constants k_2 for anion **5** and anion **6**. The nucleophilicity parameter for pyridinamide ion pairs in MeCN were obtained by analyzing the kinetic data

according to the Mayr-Patz Equation (3). They range between $N = 16.38$ ($s_N = 0.60$) for anion **3** to $N = 17.28$ ($s_N = 0.65$) for anion **4** with the only outlier being $N = 19.51$ for anion **6** due to its relatively low nucleophile-specific sensitivity parameter $s_N = 0.46$. This makes direct comparison of N values less convenient than the inspection of the second-order rate constants, which amount to $k_2 = 2.92 \times 10^4 \text{ M}^{-1} \text{ s}^{-1}$ for anion **6** and $k_2 = 3.45 \times 10^4 \text{ M}^{-1} \text{ s}^{-1}$ for anion **5** in reactions with **8a**.

Table 3. Second-order rate constants k_2 for the reactions of DMAP (**1**), TCAP (**2**), and pyridinamide salts **3a-d**, **4a**, **5a**, and **6a** with reference electrophiles **8a**, **8b**, and **8c** in MeCN (at 20 °C) analyzed by equation (3) to give the nucleophile-specific reactivity parameters N and s_N .

[a] Second-order rate constants k_2 from ref. 21,22. [b] Second-order rate constants k_2 from ref. 23. [c] Second-order rate constants k_2 from ref. 17. [d] Additional k_2 values from ref. 21–23 were used to determine N (and s_N).

Reactions of pyridinamide ion pairs **3a-d, 4-6a** with electrophiles **8** in DCM are more complex and require a slightly different approach to gain reliable reactivity parameters (for details see ref 17). We recently developed the ionic strength-controlled method where a non-nucleophilic and structurally related additive salt **7** is added to fulfill the condition of $[\text{IP}]_0 + [\text{7}] + [\text{8}] = 1.0 \text{ mM}$ in each kinetic measurement. This resulted in a linear correlation for k_{obs} for **IP** + **8** reactions in DCM in a concentration range from 0.01 – 1.0 mM. Numerical analysis of all kinetic data accounts for the fact that variable fractions of the nucleophilic pyridinamide anions **3-6** are caught in unreactive cationic sandwich complexes CAC and/or in less reactive anionic sandwich complexes ACA (see Figure 3). The rate constants k_2 collected in Table 4 for the reaction of pyridinamide ion pairs **3a-d, 4-6a** with benzhydrylium ions **8a-8c** thus reflect the reaction rates of the free anion component at $I = 1.0 \text{ mM}$. In DCM as the solvent, the bimolecular rate constant k_2 increases moderately when moving from DMAP (**1**) to TCAP (**2**). Meanwhile, we observe a significantly larger increase for pyridinamide ion pairs, which exceed those for **2** by at least one order of magnitude and the respective k_2 values obtained in MeCN by approx. two orders of magnitude.

[a] Second-order rate constants k_2 from ref. 21. [b] Second-order rate constants k_2 from ref. 17. [c] cationic sandwich association model for analysis.

Following the same mode of analysis as in Burger *et al.*¹⁷ for our library of pyridinamide ion pairs, we find the four measured rate constants k_2 for anion **3** to be again largely similar for the systems **3a-3d**, the spread of individual values now being somewhat larger at $\pm 23\%$ as compared to acetonitrile. Closer inspection shows the bimolecular rate constants for anion **3** in ion pairs **3a** and **3b** to be quite similar, as are the rate constants for ion pairs **3c** and **3d**. As already found in MeCN, the anion reactivity order in DCM is anion **3** < anion **6** < anion **5** \approx anion **4**. These measurements establish pyridinamide ion pairs as potent and exceedingly nucleophilic pyridine derivatives in solvents of low polarity (Figure 4). Pyridinamide ion pair **4a** displays the highest nucleophilicity, which is in full agreement with the results for selected benchmark reactions performed in CDCl_3 as solvent.^{15,16} The pyridinamide ion pairs studied here are thus significantly more reactive in DCM as the reaction medium as compared to cyclic guanidines such as 1,5,7-

triazabicyclo[4.4.0]dec-5-ene (TBD) identified in earlier studies as the most reactive N-nucleophiles with $N/s_N = 16.16/0.75$.³⁴

Figure 4. Mayr nucleophilicity parameter N (and s_N) of DMAP (1), TCAP (2), and pyridinamide ion pairs in MeCN and DCM, where all nucleophilicities for ion pairs were obtained by applying the mixed sandwich ion model (3b and 3d) obtained with CAC model extension).

Testing for catalytic efficiency. The reaction of *n*-butanol (10) with *p*-tolyl isocyanate (9) to urethane 11 was used as a primary benchmark reaction in earlier studies.¹⁵ The procedure established by Helberg *et al.*¹⁵ was followed to determine the effective rate constants k_{eff} for the newly synthesized pyridinamide ion pairs. The role of Lewis base catalysts in this reaction may involve both, the initial Lewis base addition to the isocyanate, or the Lewis base complexation of reactant alcohols.²⁴⁻²⁷

Scheme 1. Reaction of *n*-butanol (10) with *p*-tolyl isocyanate (9) employed as catalytic benchmark reaction.

Reaction progress was quantified by ¹H NMR spectroscopy via integration of well-separated signals. Effective rate constants were obtained by numerical simulations of the turnover curves based on an effective second-order mechanism as described in Helberg *et al.*¹⁵ TCAP (2) is the most reactive neutral

organocatalyst and, as expected based on the nucleophilicity measurements, pyridinamide salt 4a catalyzes the urethane reaction three times faster than TCAP (2), followed by salt 5a and 6a on the scale of effective rate constants k_{eff} (Figure 5). As previous kinetic measurements indicated, 3c is the least catalytically active ion pair catalyst and close to DMAP (1).

Figure 5. Effective rate constants k_{eff} for the benchmark reaction shown in Scheme 1 with 3.0 mol% of catalyst. Data for 1, 2, 3c, and 4a were taken from ref. 15.

The effective rate constants k_{eff} obtained in the catalytic benchmark reaction for pyridinamide salts correlate linearly with the rate constants k_2 determined for the reaction with benzhydryl cation 8a as shown in the double logarithmic plot in Figure 6. The good fidelity of this correlation implies that neither the change in solvent from DCM to CDCl₃ nor the change in concentration regime is of major importance for the systems studied here. The reactivity parameters obtained from the ionic-strength-controlled benzhydrylium method can, either in form of the individual k_2 values or in their condensed form as N/s_N parameters, thus be expected to be highly useful in the development and analysis of Lewis-base mediated catalytic reactions involving pyridinamide ion pair catalysts.

Figure 6. Correlation of $\log k_{\text{eff}}$ vs. $\log k_2(8a)$ for pyridinamide ion pair catalysts.

pK_a Values. In order to test whether the reactivities of pyridinamide anions 3 - 6 towards electrophiles correlate with their Brønsted basicities, their pK_a values were determined in three water/co-solvent mixtures using a spectrophotometric titration method at 25 °C (Table 5, for details see SI). The ionic strength was controlled with KCl in the buffer solution and set to $I = 0.3$ M. Starting from the neutral pyridine sulfonamide (PA), a first pK_a value (referred to as pK_{a1}) can be determined for protonation at the sulfonamide nitrogen atom, while the second pK_a value (referred to as pK_{a2}) describes deprotonation towards anions 3-6. That neutral sulfonamides PA have a preference for the imino tautomeric form shown in Table 5 is supported by X-ray crystal structures of these systems.¹⁵ The assignment of tautomeric form PA_H is only tentative and rests on X-ray crystal structures of complexes of PA with protic solvents. The UV/Vis absorbance of the substrate is measured across the full pH

range. For pK_{a2} , the pH -absorbance plot is fitted to equation 4, where A_{obs} is the observed absorbance, A_{max} is the maximum absorbance of the neutral compound, A_{min} is the minimum absorbance (at which the substrate is fully deprotonated), pH is that of the used buffer, and K_a is the acid dissociation constant for the substrate.

$$A_{obs} = \frac{10^{-pH} \times A_{max} + K_a \times A_{min}}{10^{-pH} + K_a} \quad (4)$$

The pK_a of the pyridinamide compounds was determined in aqueous solutions, H₂O/MeCN mixtures (volume ratio = 1:1), and H₂O/DMSO mixtures (volume ratio = 1:1). The pK_a of DMAP was chosen as a reference and is in agreement with literature values.²⁸ To exclude a potential interference of the counter-cation when using pyridinamide salts instead of neutral sulfonamide for the pK_a determination, pyridinamide ion pair **5a** was measured under the same conditions (see SI, Chapter 6).

Table 5. List of measured pK_a values for pyridinamides (PA) in selected aqueous solvent mixtures at 25 °C.

[a] averaged pK_a values over two measurement series. [b] conversion factor -0.257 for 50% MeCN²⁹ content applied on pH of the baseline. [c] single measurement series of observed pK_a with 50% DMSO content.

The observed pK_a values of sulfonamides were similar in all employed solvent mixtures with sulfonamide **4** being the most basic one in all cases. The overall basicity trend **3** < **6** < **5** < **4** also remains the same when switching solvents. Contrary to the sulfonamides, the pK_a value of DMAP responds strongly to changes in solvent: moving from almost pure water to the 1:1 water/MeCN mixture lowers the pK_a value from +9.85 to +8.73. Correlating the measured pK_a values of the sulfonamides in the 1:1 H₂O/MeCN solvent mixture with the logarithmic rate constant for reactions of pyridinamide ion pairs with electrophile **8a** in MeCN shows a good correlation. This correlation, however, is not universal as adding DMAP (**1**) to the dataset shows (Fig. 7).

Figure 7. A) Correlation of $\log(k_{eff})$ vs. pK_{a2} values in H₂O/MeCN = 1:1 for pyridinamide ion pairs **3a-c**, **4-6a** and pK_{a1} of DMAP (**1**). B) Correlation of $\log(k_{2,8a})$ in MeCN vs. pK_{a2} values in H₂O/MeCN = 1:1 for pyridinamide ion pair **3a-d**, **4-6a** and pK_{a1} of DMAP (**1**). The results for DMAP were excluded from the correlation in both cases.

Computational studies. To quantify the Lewis basicity of pyridinamide ion pairs, methyl cation affinities (MCA) have been calculated at the SMD(DCM)/B3LYP-D3/6-31+G(d) level of theory. This type of relative affinity value has previously been shown to correlate well with experimentally determined rate constants.^{15,30,31} In agreement with those studies, pyridine was chosen as reference base for the group transfer reaction shown in eq. 5 and the relative Lewis basicity towards Me⁺ (ΔMCA) was calculated as the free reaction energy at 298.15 K.

The resulting ΔMCA values are plotted against the experimentally obtained effective rate constant k_{eff} for the synthesis of urethane **11** with a catalyst load of 3.0 mol% in Figure 8, which shows a strong correlation between those two parameters. The relative Lewis basicity parameter ΔMCA displays the same general trend observed for the nucleophilicity, pK_a values and in the effective rate constant k_{eff} in the urethane benchmark reaction. In all measurements the most basic pyridinamide ion pair **4a** achieves the highest value. It should be added that higher catalyst basicity may³² or may not³³ translate into higher reaction rates of catalytic transformations with pyridine-derived Lewis bases.

Figure 8. A) Correlation of effective rate constant $\log(k_{\text{eff}})$ for urethane synthesis (3.0 mol% catalyst loading) with Lewis basicity parameter ΔMCA , and B) correlation of bimolecular rate constant $\log(k_{2,8a})$ with Lewis basicity parameter ΔMCA calculated at the SMD(DCM)/B3LYP-D3/6-31+G(d) level of theory. The results for DMAP were excluded from the correlation in both cases.

CONCLUSION

By employing a combination of conductivity, DOSY NMR, and kinetic measurements for a focused library of pyridinamide ion pairs, we were able to elucidate the complex asymmetric association behavior of these ions and its impact on their catalytic performance. Key insights include the strong dependence of the association pattern on the size and structure of the cation, which significantly influences the balance between cationic and anionic sandwich association. The association constants of ion pair **3a-d** derived from conductivity data revealed a lower degree of association in ion pairs with larger aryl substituted cation, which also correlates with their catalytic activity. DOSY NMR results further support this theory and show a predominant cationic sandwich association in smaller anion – larger cation volume pairs, which is essential for maintaining a higher concentration of free nucleophilic anions in solution.

Kinetic studies using the ionic strength-controlled benzhydrylium method confirmed a superior nucleophilicity of pyridinamide anions in DCM compared to neutral organocatalysts such as TCAP (**2**). Comparing the bimolecular rate constants k_2 for reactions with cationic reference electrophiles reveal the most nucleophilic pyridinamide compound being anion **4** with a 90 times higher rate constant than TCAP (**2**). This is also reflected in the determined reaction rate of urethane benchmark reaction, where **4a** catalyzes the reaction seven times more effectively than TCAP (**2**). Kinetic data for the single step nucleophilicity measurements as well as the multi-step catalytic benchmark experiments correlate well with the Brønsted and Lewis basicities of the respective ion pair systems. These latter quantities thus represent, together with the volume parameters obtained from SMD-type calculations, valuable guidelines for the future design of highly reaction ion pair systems.

3.1 Supplementary Data

3.1.1 General Information

All reagents were purchased from Sigma Aldrich, TCI, or Acros and used without further purification unless otherwise noted. Solvents were obtained from Acros Organics, Sigma Aldrich, or Merck and purified by simple distillation in a rotary evaporator, unless otherwise specified.

All air- and moisture-sensitive reactions were performed under a nitrogen atmosphere and the glassware and magnetic stirrers were dried in a dry oven at 110 °C overnight.

CH₂Cl₂ for nucleophilicity measurements was stirred over concentrated H₂SO₄ for two weeks before extraction with water (1 x 1.0 L), NaHCO₃ (1 x 1.0 L), and again water (1 x 1.0 L). CaH₂ was added as a drying agent, and the solvent was freshly distilled over CaH₂ prior to use.

Melting points were acquired using Büchi Melting Point M-560 devices and are uncorrected.

Nuclear magnetic resonance (NMR) spectra were recorded on a Bruker 400 MHz or INOVA 400 and 600 MHz machine. The following abbreviations were used in the analysis of NMR spectra: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, br s = broad singlet. NMR signals were assigned based on 2D spectra (COSY, HSQC, HMBC) analysis. Chemical shifts are given in ppm. The internal reference was set to the residual solvent signals (CD₂Cl₂, CDCl₃, DMSO-d₆). The ¹³C NMR spectra (101 or 151 MHz) were recorded under broadband proton-decoupling. ¹⁹F NMR spectra were referenced using the solvent signal.^[1] The spectra were imported and processed in the program MestreNova (version 14.1.1).

Infrared (IR) spectra were measured on a Perkin Elmer Spectrum BX-59343 instrument with a Smith Detection DuraSamplIR II Diamond ATR sensor for liquids or neat for solids. Intensities are described as vs = very strong, m = medium, w = weak, br = broad.

High-resolution mass spectra (HRMS) were recorded on a Thermo Finnigan LTQ FT Ultra Fourier Transform Ion Cyclotron Resonance mass spectrometer with electrospray ionization (ESI) for sample ionization. For EI (70 eV) measurements a Thermo Finnigan of the MAT 95 type with a direct exposure probe (DEP) was used.

Crystal structures were recorded using an Oxford Diffraction XCalibur with Sapphire CCD-detector and a molybdenum-K_α-source (λ = 0.71073) with a concentric circle kappa-device. The structures were resolved using the program SHELXS or SIR97 and refined with SHELXS.

3.1.2 Additional Figures and Correlations

Conductivity profiles in MeCN for all pyridinamide ion pairs are depicted in Figure 3.1.

Figure 3.1: [Figure S1]. A) Conductivity profiles for **3a-d** measured in MeCN at 20 °C, B) Conductivity profiles for **3-6a** measured in MeCN at 20 °C.

The association constant K_{IP} for the association in MeCN was determined according to the simple 1:1 ion association model described in Zipse *et al.*^[2] The resulting association constants K_{IP} (M^{-1}) are summarized in Table 3.1.

Table 3.1: [Table S1]. Association constants K_{IP} (M^{-1}) of pyridinamide ion catalysts **3a-d, 4-6a** at 20 °C in MeCN.

System	Δ_m ($\text{S cm}^2 \text{mol}^{-1}$)	K_{IP} (M^{-1})
3a	126	34.6 ± 0.29
3b	130	50.6 ± 0.50
3c	133	44.0 ± 0.63
3d	129	44.0 ± 0.34
4a	110	42.9 ± 0.33
5a	113	44.5 ± 0.80
6a	115	49.3 ± 0.55

Additional correlations were performed for $\text{p}K_{\text{a}}$ values with the respective effective rate constants of the urethane benchmark reaction. Both experimental values correlate strongly with each other in Figure 3.2, however, adding the results of DMAP to the data set demonstrated that this is not a universal correlation for pyridine-based compounds.

Figure 3.2: [Figure S2]. Correlation of A) $\log(k_{2,8a})$ in MeCN, B) $\log(k_{2,8b})$ in MeCN, C) $\log(k_{2,8c})$ in MeCN, D) $\log(k_{2,8a})$ in DCM, E) $\log(k_{2,8b})$ in DCM, and F) $\log(k_{2,8c})$ in DCM with pK_a values measured in $H_2O/MeCN = 1:1$ for pyridinamide salts **3-6a**.

Figure 3.3: [Figure S3]. Correlation of A) bimolecular rate constant $\log(k_{2,8a})$, B) bimolecular rate constant $\log(k_{2,8b})$, C) bimolecular rate constant $\log(k_{2,8c})$ with Lewis basicity parameter ΔMCA calculated at the SMD(DCM)/B3LYP-D3/6-31+G(d) level of theory.

In Table 3.2 and Table 3.3 below the most important results of the conductivity data analysis is summarized to enable a quick and easy overview over the specific molar conductivities Λ_m ($S\text{ cm}^2\text{ mol}^{-1}$), the limited molar ion conductivities λ_i ($S\text{ cm}^2\text{ mol}^{-1}$) of all charged species, their scaling factors δ_i and the resulting association constant of all applied model (see Chapter 2.1.4 and 3.1.4 for details).

Table 3.2: [Table S2]. List of specific molar conductivities Λ_m ($S\text{ cm}^2\text{ mol}^{-1}$) with the corresponding limited molar ionic conductivities λ_i ($S\text{ cm}^2\text{ mol}^{-1}$) with their scaling factor δ_i of all charged species and the resulting ion association constant K_{IP} (M^{-2}), the cationic and anionic sandwich association constants K_{CAC} and K_{ACA} (M^{-2}) with the respective RMSE values for all pyridinamide ion pairs.

3.1.3 Synthesis of Compounds

In this supporting information the data for the following ion pair (see Chart 3.1) will be discussed. Pyridinamide ion pair **3a** will be used as reference system. Synthetic procedures for compounds PA_3, PA_4, ion pair **3a**, **4a**, and additive **6** (in this chapter **7a**) can be found in Chapter 2.1

Chart 3.1: [Chart S1]. Pyridinamide ion pair library.

3.1.3.1 Synthesis of Neutral Pyridinamides

4-Methyl-*N*-(pyridin-4(1*H*)-ylidene)benzenesulfonamide (PA_5)

Following a modified procedure of Helberg and Zipse,^[3] 4-aminopyridine (2.00 g, 1.0 eq, 21.3 mmol) was dissolved in pyridine (22.0 mL). Triethylamine (8.00 mL, 57.4 mmol, 2.3 eq) was added and the mixture was stirred for 10 min. After cooling to 0 °C, 4-methylbenzenesulfonyl chloride (4.86 g, 1.2 eq, 25.5 mmol) was added and the mixture was stirred at 0 °C for 30 min. Subsequently, the reaction mixture was refluxed for 3 h before being cooled down to rt. The solvent was evaporated, and the crude product was suspended in H₂O, refluxed for 20 min and filtered while hot. This process was repeated with ethanol and MTBE, yielding pyridinamide **5** (4.78 g, 19.59 mmol, 91%) as an off-white solid.

¹H NMR (400 MHz, DMSO-*d*₆): δ [ppm] = 12.3 (s, 1H), 8.01 (d, *J* = 6.7 Hz, 2H), 7.71 – 7.65 (m, 2H), 7.30 (d, *J* = 8.0 Hz, 2H), 6.95 – 6.86 (m, 2H), 2.33 (s, 2H).

¹³C NMR (101 MHz, DMSO-*d*₆): δ [ppm] = 141.6, 140.2, 129.3, 126.2, 114.1, 20.9.

HRMS (ESI): calc. for C₁₂H₁₂N₂O₂S⁺ [*M*⁺]: 248.0614, found: 248.0614.

The spectroscopic data is consistent with the literature.^[3]

N-(pyridin-4(1*H*)-ylidene)-4-(trifluoromethyl)benzenesulfonamide (PA_6)

4-Aminopyridine (1.00 g, 10.6 mmol, 1.0 eq) was dissolved in dry pyridine (12.0 mL) under nitrogen atmosphere. Triethylamine (3.30 mL, 23.4 mmol, 2.2 eq) was added and the reaction mixture was stirred for 10 min before being cooled down to 0 °C. 4-Trifluoromethylbenzenesulfonyl chloride (2.86 g, 11.7 mmol, 1.1 eq) was added and the mixture was stirred for 20 min before being refluxed for 2.5 h. The solvent was evaporated, and the crude product was suspended in H₂O, refluxed for 20 min and filtered while hot. This process was repeated with ethanol and MTBE, yielding pyridinamide **6** (2.64 g, 8.73 mmol, 82%) as an off-white solid.

^1H NMR (400 MHz, $\text{DMSO}-d_6$): δ [ppm] = 12.8 (s, 1H), 8.00 (dd, J = 7.6, 5.4 Hz, 4H), 7.87 (d, J = 8.2 Hz, 2H), 6.94 (d, J = 7.3 Hz, 2H).

^{13}C NMR (101 MHz, $\text{DMSO}-d_6$): δ [ppm] = 162.5, 147.8, 139.2, 131.0 (q, J = 32.1 Hz), 126.9, 125.9 (q, J = 3.8 Hz), 123.7 (q, J = 272.6 Hz), 114.9.

^{19}F NMR (377 MHz, CDCl_3): δ [ppm] = -61.4

IR (ATR): ν (cm^{-1}) = 3049 (w), 2660 (w), 1635 (m), 1617 (m), 1477 (s), 1330 (s), 1194 (m), 1140 (vs), 1086 (s), 950 (s), 834 (s), 766 (m), 706 (m).

HRMS (ESI): calc. for $\text{C}_{12}\text{H}_9\text{F}_3\text{N}_2\text{O}_2\text{S}^+ [\text{M}^+]$: 302.0331, found 302.0335.

m. p: 298-301 °C

3.1.3.2 Synthesis of Pyridinamide Ion Pairs

Triphenyl ((triphenyl- λ 5-phosphaneylidene)amino) phosphonium pyridin-4-yl (trifluoromethyl) sulfonyl amide (**3b**)

Pyridinamide **3** (349 mg, 1.55 mol, 1.0 eq) was added to a solution of NaOH (67.0 mg, 1.70 mmol, 1.1 eq) in H_2O (5.00 mL). Bis-(triphenylphosphoranylidene)-ammonium chloride (886 mg, 1.55 mmol, 1.0 eq) was added, and the reaction mixture was stirred at rt. overnight. DCM (5.00 mL) was added, and the two phases were separated. The aqueous phase was extracted with DCM (3 x 15 mL). The collected organic phase was dried over MgSO_4 , filtered and the solvent was evaporated. The crude product was crystallized from DCM overlaid with toluene in a 250 mL flask closed with a septum with one inserted needle, cooled to -40 °C (CO_2/MeCN) and left in the cooling bath overnight. Ion Pair **3b** (952 mg, 1.25 mmol, 81%) was obtained in form of colorless crystals.

^1H NMR (400 MHz, CDCl_3): δ [ppm] = 8.10 (d, J = 6.6 Hz, 2H), 7.63 (td, J = 5.7, 2.6 Hz, 6H), 7.49 – 7.38 (m, 24H), 7.12 (d, J = 6.5 Hz, 2H).

^{13}C NMR (101 MHz, CDCl_3): δ [ppm] = 156.3, 149.4, 134.08 – 133.82 (m), 132.41 – 131.92 (m), 129.99 – 129.37 (m), 127.1 (dd, J = 107.9, 1.9 Hz), 122.3 (q, J = 328.7 Hz), 118.1.

^{19}F NMR (376 MHz, CDCl_3): δ [ppm] = -76.8.

^{31}P NMR (162 MHz, CDCl_3): δ [ppm] = 21.03.

IR (ATR): ν (cm^{-1}) = 3058 (br), 1588 (m), 1438 (m), 1319 (s), 1288 (vs), 1198 (s), 1155 (s), 1115 (s), 999 (m), 832 (w), 723 (s), 692 (m).

Elemental Analysis: $\text{C}_{42}\text{H}_{34}\text{F}_3\text{N}_3\text{O}_2\text{P}_2\text{S}$ (763.76 g/mol): calc. (%) C, 66.05; H, 4.49; N, 5.50; S, 4.20; Found (%) C, 65.84; H, 4.56; N, 5.43; S, 4.21.

HRMS (ESI): calc. for $\text{C}_6\text{H}_4\text{F}_3\text{N}_2\text{O}_2\text{S}^- [\text{A}^-]$: 224.9951; found 224.9952; calc. for $\text{C}_{36}\text{H}_{30}\text{NP}_2^+ [\text{C}^+]$: 538.1848; found: 538.1849.

Tetrabutylammonium pyridin-4-yl((trifluoromethyl)sulfonyl)amide (**3c**)

Following a modified procedure of Helberg and Zipse,^[3] pyridinamide **3** (400 mg, 1.77 mmol, 1.0 eq) was added to a solution of NaOH (76.3 mg, 1.91 mmol, 1.0 eq) in H₂O (6.00 mL). Tetrabutylammonium bromide (570 mg, 1.77 mmol, 1.0 eq) was added portion-wise. The resulting reaction mixture was stirred at rt. overnight. DCM (6 mL) was added, and the two phases were separated. The aqueous phase was extracted with DCM (3 x 15 mL) and the collected organic phase was dried over MgSO₄, filtered, and concentrated *in situ*. The crude product was crystallized from DCM overlayed with toluene and heptane. Pyridinamide ion pair **3c** (710 mg, 1.52 mmol, 86%) were obtained in form of off-white crystals.

¹H NMR (600 MHz, CDCl₃): δ [ppm] = 8.16 (d, *J* = 6.4 Hz, 2H), 7.04 (d, *J* = 6.4 Hz, 2H), 3.16 – 3.08 (m, 8H), 1.58 – 1.51 (m, 8H), 1.36 (h, *J* = 7.3 Hz, 8H), 0.95 (t, *J* = 7.4 Hz, 12H).

¹³C NMR (151 MHz, CDCl₃): δ [ppm] = 155.8, 149.6, 122.1 (q, *J* = 328.2 Hz), 118.1 58.8, 24.0, 19.7, 13.7.

¹⁹F NMR (377 MHz, CDCl₃): δ [ppm] = -76.8.

EA: C₂₂H₄₀F₃N₃O₂S (467.64 g/mol): calc. (%): C, 56.51; H, 8.62; N, 8.99; S, 6.86; Found (%): C, 56.34; H, 8.45; N, 9.00; S, 6.63.

The spectroscopic data is consistent with the literature.^[3]

Tetrabutylphosphonium pyridin-4-yl((trifluoromethyl)sulfonyl)amide (**3d**)^[3]

Pyridinamide **3** (402 mg, 1.78 mmol, 1.0 eq) was suspended in tetrabutylphosphonium hydroxide (1.25 mL, 40% in H₂O, 1.78 mmol, 1.0 eq) and H₂O (5.00 mL) was added. The reaction mixture was stirred at rt. for 2 h. DCM (5.00 mL) was added, and the two phases were separated. The aqueous phase was extracted with DCM (3 x 15 mL). The collected organic phase was dried over MgSO₄, filtered and the solvent was evaporated. The crude product was crystallized from DCM overlayed with toluene, *iso*-hexane (1.00 mL), and heptane (2.50 mL). The mixture was stored in the fridge overnight. Ion Pair **3d** (718 mg, 1.48 mmol, 88%) was obtained in form of off-white crystals.

¹H NMR (600 MHz, CDCl₃): δ [ppm] = 8.17 (d, *J* = 6.4 Hz, 2H), 7.04 (d, *J* = 6.5 Hz, 2H), 2.18 – 2.08 (m, 8H), 1.49 – 1.43 (m, 16H), 0.96 – 0.90 (m, 12H).

¹³C NMR (151 MHz, , CDCl₃): δ [ppm] = 155.6, 149.7, 122.1 (q, *J* = 328.1 Hz), 118.1, 23.9 (d, *J* = 15.3 Hz), 23.7 (d, *J* = 4.8 Hz), 18.7 (d, *J* = 47.5 Hz), 13.4.

¹⁹F NMR (376 MHz, CDCl₃): δ [ppm] = -76.84.

³¹P NMR (162 MHz, CDCl₃): δ [ppm] = 32.98.

Elemental Analysis: C₂₂H₄₀F₃N₂O₂PS (484.60 g/mol): calc. (%) C, 54.53; H, 8.32; N, 5.78; S, 6.62; Found (%): C, 54.41; H, 8.41; N, 5.67; S, 6.89.

The spectroscopic data is consistent with the literature.^[3]

Tetraphenylphosphonium pyridin-4-yl(tosyl)amide (5a)

Pyridinamide **5** (449 mg, 1.81 mmol, 1.0 eq) was added to a solution of NaOH (74.3 mg, 1.86 mmol, 1.1 eq) in H₂O (5.00 mL). Tetraphenylphosphonium bromide (746 mg, 1.78 mmol, 1.0 eq) was dissolved in DCM and added dropwise over 10 min through a dropping funnel. The reaction mixture was stirred at rt. for 2 h. DCM (5.00 mL) was added, and the two phases were separated. The aqueous phase was extracted with DCM (3 x 15 mL). The collected organic phase was dried over MgSO₄, filtered and the solvent was evaporated. The crude product was crystallized from DCM overlaid with toluene while stored in the fridge. Ion Pair **5a** (905 mg, 1.54 mmol, 85%) was obtained in form of colorless crystals.

¹H NMR (400 MHz, CDCl₃): δ [ppm] = 7.90 – 7.80 (m, 8H), 7.75 (td, *J* = 7.8, 3.6 Hz, 8H), 7.64 – 7.54 (m, 8H), 7.08 (d, *J* = 7.8 Hz, 2H), 6.76 – 6.72 (m, 2H), 2.28 (s, 3H)

¹³C NMR (101 MHz, CDCl₃): δ [ppm] = 157.9, 148.6, 143.4, 139.5, 135.91 (d, *J* = 3.0 Hz), 134.48 (d, *J* = 10.3 Hz), 130.91 (d, *J* = 12.9 Hz), 128.7, 126.9, 117.5 (d, *J* = 89.6 Hz), 116.2, 21.4.

³¹P NMR (162 MHz, CDCl₃): δ [ppm] = 23.08.

IR (ATR): ν (cm⁻¹) = 3958 (br), 2177 (br), 1586 (m), 1483 (m), 1437 (m), 1314 (m), 1246 (m), 1127 (s), 1107 (s), 1083 (s), 990 (m), 816 (w), 722 (vs), 689 (s).

Elemental Analysis: C₃₆H₃₁N₂O₂PS (586.69 g/mol): calc. (%) C, 73.70; H, 5.33; N, 4.77; S, 5.46; Found (%): C, 73.02; H, 5.45; N, 4.59; S, 5.66.

m. p: 160-165 °C

Tetraphenylphosphonium pyridin-4-yl((4-(trifluoromethyl)phenyl)sulfonyl)amide (6a)

Pyridinamide **6** (299 mg, 0.99 mmol, 1.0 eq) was added to a solution of NaOH (40.0 mg, 1.00 mmol, 1.1 eq) in H₂O (5.00 mL). Tetraphenylphosphonium bromide (415 mg, 0.99 mmol, 1.0 eq) was added and the reaction mixture was stirred at rt. overnight. DCM (5.00 mL) was added, and the two phases were separated. The aqueous phase was extracted with DCM (3 x 10 mL). The collected organic phase was dried over MgSO₄, filtered and the solvent was evaporated. The crude product was crystallized from DCM overlaid with toluene and heptane (0.50 mL) while stored in the fridge. The obtained crystals were dissolved in little DCM and the solvent was removed *in vacuum*, yielding a colorless foam that was dried under N₂ for two days. Ion Pair **6a** (537 mg, 0.84 mmol, 85%) was obtained as a colorless solid.

¹H NMR (400 MHz, CDCl₃): δ [ppm] = 8.06 – 8.01 (m, 1H), 7.92 – 7.83 (m, 3H), 7.73 (td, *J* = 7.9, 3.6 Hz, 4H), 7.61 – 7.49 (m, 5H), 6.81 (d, *J* = 5.5 Hz, 1H).

¹³C NMR (101 MHz, CDCl₃): δ [ppm] = 157.5, 150.3, 148.9, 135.95 (d, *J* = 3.1 Hz), 134.45 (d, *J* = 10.3 Hz), 130.9 (d, *J* = 12.9 Hz), 127.3, 125.15 (q, *J* = 3.8 Hz), 124.1 (*virt.* q, *J* = 272.3 Hz, CF₃), 117.55 (d, *J* = 89.5 Hz), 166.4.

³¹P NMR (162 MHz, CDCl₃): δ [ppm] = 23.09.

Tetrabutylphosphonium tetrafluoroborate (**7d**)

$\text{PBU}_4^+ \text{BF}_4^-$ Tetrabutylphosphonium hydroxide (1.91 g, 40% in H_2O , 1.77 mmol, 1.0 eq) was added to a solution of sodium tetrafluoroborate (303 mg, 2.77 mmol, 1.0 eq) in H_2O (10.0 mL). The resulting cloudy suspension was stirred for 2 h at rt. DCM (10.0 mL) was added, and the two phases were separated. The aqueous phase was extracted with DCM (3 x 20 mL). The collected organic phase was dried over $MgSO_4$, filtered and the solvent was evaporated. The crude product was dissolved in DCM and the solvent evaporated until dryness. Product **7d** (958 mg, 1.45 mmol, 52%) was further dried *in vacuum*, resulting in a colorless solid.

3.1.4 Conductometric Measurements

For the measurement, a 0.02 M stock solution of the respective catalyst was prepared in a 10 mL volumetric flask and was given portion-wise to the pure solvent in a measuring cell at 20 °C. Conductivity measurements were performed using a WTW conductometer with a Pt electrode LTA 1/NS in MeCN and DCM. Calibration was done as described in ref. [4]. Temperature control (20.0 ± 0.1 °C) was achieved by using a circulating bath cryostat. The conductivity was measured in volts (V) and depicted in “ME-REDLab Data Acquisition V1.1”, developed by Dr. B. Kempf 2010, where the conductivity was plotted against time. After adding a portion of salt stock solution, one must wait until the conductivity value reaches a stable plateau (min 30 sec up to 100 sec) from which the average conductivity value is read off. In Excel this value (V) was converted into ($\mu\text{S cm}^{-1}$) by multiplying it with the cell parameter of the used electrode ($z = 160$). The cell parameter was obtained by calibrating the conductometric set up with aqueous KCl solutions (0.007 M, 0.0145 M, and 0.0375 M; commercial conductivity standard solutions purchased from Alfa Aesar) referring to the conductivity of $1273 \mu\text{S cm}^{-1}$ for an 0.01 M solution of aq. KCl at 20 °C.^[5]

3.1.4.2 Conductivity Data Analysis

The conductivity of a substance is defined as its ability to conduct electricity and depends on the number of charge carrier in solution. Therefore, it can be expressed as a molar quantity where κ is the measured conductivity, Λ_m is the molar conductivity and c is the measured concentration of electrolyte.

$$\kappa = \Lambda_m c \quad (3.1)$$

The experimentally determined conductivity κ depends on the specific molar conductivity Λ_m of the measured salt and the ion concentration $[X]$ as expressed in eq. 3.2.

$$\kappa = \Lambda_m [X] \quad (3.2)$$

The molar conductivity Λ_m consists of the sum of all limited molar ionic conductivities λ_i of all ionic species i in solution according to eq. 3.3.

$$\Lambda_m = \sum \lambda_i \quad (3.3)$$

The value for the specific molar conductivity Λ_m for the combined ions is derived from the extrapolated linear regression line of the red marked conductivity values (first three data points) assuming that the respective measured salt is fully dissociated in this concentration area (see Figure 3.4). Therefore, the specific molar conductivity Λ_m can be divided into the limited molar ionic conductivity of the cation λ_{cat} and of the anion λ_{an} . The limited molar ionic conductivities are determined by applying Fuoss' theory that the limited molar conductivity λ of each ion is proportional to their volume.^[6,7] By using the calculated volumes of each anion, cation, and ion pair based on the Van der Waals cavities employed in the SMD continuum solvation model at the SMD(DCM)/B3LYP-D3/6-31+G(d) level of theory the scaling factor δ_i for the conversion of Λ_m into λ_i of the respective anion **A** and cation **C** was obtained (see eq. 3.4).

$$\delta_A = \frac{\text{vol}(\text{A})}{\text{vol}(\text{IP})} \quad (3.4a)$$

$$\delta_C = \frac{\text{vol}(\text{C})}{\text{vol}(\text{IP})} \quad (3.4b)$$

The background conductivity (BG) included here is the conductivity of the used solvent (BG = $0.8 \mu\text{S cm}^{-1}$).

Figure 3.4: [Figure S4]. Concentration-dependent conductivity profile for catalyst **3a** in DCM with $\Lambda_m = 79.2 \text{ S cm}^2 \text{ mol}^{-1}$ and solvent background BG = $0.80 \text{ } \mu\text{S cm}^{-1}$ at 20°C .

Determination of the respective association constants were achieved by numerical simulation utilizing the complex pathway simulation program, COPASI^[8], for the analysis of the conductivity data.

Therefore, a biochemical model was opened, and the to be investigated association type was described as a reaction. The reaction was set to be reversible, which is also indicated by the equal sign “=” in the reaction equation. In the “Symbol Definition” section the starting compounds are listed with rate constant k_1 as well as the product with rate constant k_2 , defining the association constant as $k_1/k_2 = K$.

For the optimization of the association constant K the reaction constant k_2 was set to be 1, while the rate constant k_1 was changed until the best fit between the simulated and experimental conductivity curve was found. The “root-mean-square-error” RMSE was used as a quality control measure.

In the section “Species” the individual concentration for all compounds were added. This was zero for the product(s) and the total salt concentration for both educts (e.g. for anion **A** and for cation **C**).

Next, in the section “Tasks” menu the “Steady-State” option was selected. By clicking the “Run” button at the bottom of the window, COPASI ran through a steady state analysis and then reported the concentration of each species of the biochemical model.

The obtained concentrations were then transferred to an excel sheet where the concentrations were converted into conductivity values according to eq. 3.5 with λ_i being the limited molar ionic conductivity of a charged species, δ_i the scaling factor of a charged species for the conversion of the specific molar conductivity Λ_m into the respective λ_i , and $[X]_i$ being the concentration of this respective charged species. The scaling factor $\delta_i = \lambda_i/\Lambda_m$ was introduced to simplify the conversion process in excel.

$$\kappa = \sum \lambda_i \times [X]_i \quad (3.5a)$$

$$\kappa = \sum \delta_i \times \Lambda_m \times [X]_i \quad (3.5b)$$

These simulated conductivity values were then compared to the experimental data. The conductivity background of the solvents was subtracted from the data points giving the conductivity of the pure salt and the RMSE was calculated as a quality control measure. The rate constant k_1 was optimized until the minimum of the RMSE was found.

This procedure was semi-automated by using a python script that automatically performs the “steady state” function for a given numbers of concentrations.^[9] The following association types were analyzed by employing numerical simulations.

3.1.4.3 Model I – Double 1:1 Ion Pair Association

The 1:1 association model included two anions **A** and two cation **C** combining into two charge-neutral non-conducting ion pairs **IP** is described in Scheme 3.1.

Scheme 3.1: [Scheme S1]. Equation for numerical simulations of double 1:1 ion association for pyridinamide ion pairs.

The 1:1 ion pair association constant was defined as $k_1/k_2 = K_{IP}$ with $k_2 = 1$ being a fixed value. The limited molar ionic conductivities for the anion and cation were calculated according to eq. 3.4, while it was assumed that the neutral ion pair does not contribute towards the overall conductivity ($\lambda_{IP} = 0.0 \text{ S cm}^2 \text{ mol}^{-1}$). The results of this model for all ion pairs systems are summarized below in Table 3.4.

Table 3.4: [Table S4]. Double ion association constants K_{IP} (M^{-2}) with the specific molar conductivities Λ_m ($\text{S cm}^2 \text{ mol}^{-1}$) and limited ionic conductivities λ_i ($\text{S cm}^2 \text{ mol}^{-1}$) and the scaling factor δ_i for pyridinamide ion pairs.

Ion Pair	Λ_m ($\text{S cm}^2 \text{ mol}^{-1}$)	δ_A	δ_C	λ_A ($\text{S cm}^2 \text{ mol}^{-1}$)	λ_C ($\text{S cm}^2 \text{ mol}^{-1}$)	K_{IP} (M^{-2})	RMSE
3d	56.0	0.40	0.60	22.4	33.6	7.35×10^6	0.329
3c	57.9	0.41	0.59	23.7	34.2	5.00×10^6	0.261
3b	80.3	0.28	0.72	22.4	57.8	2.96×10^5	0.318
3a	79.2	0.37	0.63	29.3	49.9	6.86×10^5	0.304
5a	73.2	0.42	0.58	30.7	42.5	6.92×10^5	0.228
4a	73.6	0.44	0.56	32.4	41.2	8.79×10^5	0.274
6a	74.2	0.45	0.55	33.4	40.8	6.89×10^5	0.320

While this model fit the conductivity data reasonably well, it did not concur with the DOSY NMR data. Instead of observing a convergence of the diffusion coefficients D_i ($\text{m}^2 \text{ s}^{-1}$) and hence the corresponding ion volumes, the measurements showed a clear deviation between both ions. The resulting DOSY volumes for exemplary **3a** were plotted against the used concentrations for both cation and anion (see Figure 3.5, with data from ref. [2]) and compared to simulated ion volumes calculated according to eq. 3.6 and based on the concentration obtained by numerical simulation of the 1:1 ion pair association model I.

$$\text{vol}_{\text{cat}} = \left(\frac{[C]}{[IP]_{\text{tot}}} \right) \times 362 + \left(\frac{[IP]}{[IP]_{\text{tot}}} \right) \times 570 \quad (3.6a)$$

$$\text{vol}_{\text{an}} = \left(\frac{[A]}{[IP]_{\text{tot}}} \right) \times 215 + \left(\frac{[IP]}{[IP]_{\text{tot}}} \right) \times 570 \quad (3.6b)$$

For the lowest concentrations the measured volumes were close to the calculated ones for the free ions (anion: 215 \AA^3 and cation: 362 \AA^3). For concentrations higher than 0.01 mM , a clear increase of the volumes for the anion **3** and the cation **a** was observed with a large off-set between the anion and cation volumes. If the association follows a 1:1 ion pair association the volumes of anion and cation should converge and approach 570 \AA^3 for a monomeric ion pair **3a**. Instead with increasing salt concentration the volume of the cation even exceeded the calculated volume for the 1:1 monomeric ion pair **3a** (641 \AA^3 versus 570 \AA^3 at 1.0 mM). On the other hand, the simulated volume of the cation based on the concentrations of the conductivity evaluation lay far below the calculated volume the 1:1 monomeric ion pair **3a** (435 \AA^3 versus 570 \AA^3 at 1.0 mM).

Figure 3.5: [Figure S5]. Concentration-dependent volumes of cations **a** (orange “+” symbols) and anions **3** (green “-” symbols) of salt **3a** in CD_2Cl_2 as calculated from DOSY experiments (with data from ref. [2]) with the respective free ion volumes (dotted line; cation in orange; anion in green) and the calculated trend for 1:1 ion association for each ion volume (purple dotted line).

All these observations suggested the involvement of an additional charged species.

3.1.4.4 Model IIa – Cationic Sandwich Association

Based on the finding of DOSY NMR measurements further association types were investigated. One was a cationic sandwich association consisting of four ions, two anions **A** and two cations **C** associating into a formally positive charged sandwich complex **CAC** which leaves one free anion **A** (see Scheme 3.2).

Scheme 3.2: [Scheme S2]. General cationic sandwich association equilibrium for pyridinamide ion pairs.

The cationic sandwich association constant is defined as $k_1/k_2 = K_{\text{CAC}}$ with $k_2 = 1$ being a fixed value. The limited molar ionic conductivities for the anion and cation were calculated according to eq. 3.4. However, there was no established way to determine the limited molar ionic conductivity λ_{CAC} for the cation sandwich **CAC**. Therefore, instead of assigning all sandwich cations a fixed value, it was decided to treat λ_{CAC} as another variable. This required a slight modification of the optimization process since instead of one variable, the association constant K , there were two variables to be optimized, the sandwich association constant K_{CAC} (M^{-2}) and λ_{CAC} ($\text{S cm}^2 \text{ mol}^{-1}$).

To simplify the process, the scaling factor δ_{CAC} was optimized rather than λ_{CAC} for the sandwich cation. Since the sandwich complex is formally positively charged, it is recommended to start the optimization process with $\delta_{\text{CAC}} = \delta_{\text{C}} = 0.63$ (exemplary for ion pair **3a**). The aim was to find a global minimum based on the sandwich association constant K_{CAC} with the RMSE being the quality control measure (see Table 3.5).

Table 3.5: [Table S5]. List of cationic sandwich association constants K_{CAC} (M^{-2}) and scaling factor δ_{CAC} of the optimization process to find the global minimum for both parameters for pyridinamide ion pair **3a** with its specific molar conductivity Λ_{m} ($\text{S cm}^2 \text{mol}^{-1}$) and the limited ionic conductivities λ_i ($\text{S cm}^2 \text{mol}^{-1}$) for anion **3** and cation **a**.

Ion Pair	Λ_{m} ($\text{S cm}^2 \text{mol}^{-1}$)	$\delta_{\text{A}}/\delta_{\text{C}}$	δ_{CAC}	K_{CAC} (M^{-2})	RMSE
3a	79.2	37/63	0.66	6.06×10^6	0.1741
				6.07×10^6	0.1740
				6.08×10^6	0.1741
			0.67	6.37×10^6	0.1735
				6.38×10^6	0.1734
				6.39×10^6	0.1735
			0.68	6.69×10^6	0.1787
				6.70×10^6	0.1786
				6.71×10^6	0.1787

The obtained sandwich association constants for all ion pair systems are summarized in Table 3.6.

Table 3.6: [Table S6]. Cationic sandwich association constants K_{CAC} (M^{-2}) with the specific molar conductivities Λ_{m} ($\text{S cm}^2 \text{mol}^{-1}$) and the scaling factor δ_i of all charged species for pyridinamide ion pairs.

Ion Pair	Λ_{m} ($\text{S cm}^2 \text{mol}^{-1}$)	$\delta_{\text{A}}/\delta_{\text{C}}/\delta_{\text{CAC}}$	K_{CAC} (M^{-2})	RMSE
3d	56.0	40/60/15	1.07×10^7	0.094
3c	57.9	41/59/22	1.01×10^7	0.100
3b	80.3	28/72/91	4.65×10^6	0.105
3a	79.2	37/63/67	6.38×10^6	0.173
5a	73.2	42/58/57	5.15×10^6	0.130
4a	73.6	44/56/54	6.50×10^6	0.122
6a	74.2	45/55/60	6.75×10^6	0.161

In comparing the RMSE value obtained for the 1:1 ion pair association and the cationic sandwich association, a better fit for the cationic sandwich association model was observed. As a secondary quality control measure, the ion volumes based on DOSY NMR were compared to ion volumes calculated based on the numerical simulation data. Therefore, the anion and cation volumes were calculated according to eq. 3.7.

$$\text{vol}_{\text{cat}} = \left(\frac{[\text{C}]}{[\text{IP}]_{\text{tot}}} \right) \times 362 + \left(\frac{2 \times [\text{CAC}]}{[\text{IP}]_{\text{tot}}} \right) \times 925 \quad (3.7a)$$

$$\text{vol}_{\text{an}} = \left(\frac{[\text{A}]}{[\text{IP}]_{\text{tot}}} \right) \times 215 + \left(\frac{[\text{CAC}]}{[\text{IP}]_{\text{tot}}} \right) \times 925 \quad (3.7b)$$

Figure 3.6 shows the data and model comparison for ion pair **3a** as an example.

Figure 3.6: [Figure S6]. Concentration-dependent volumes of cations **a** (orange “+” symbols) and anions **3** (green “-” symbols) of salt **3a** in CD₂Cl₂ as calculated from DOSY experiments (with data from ref. [2]) with the respective free ion volumes (dotted line; cation in orange; anion in green), the calculated trend for 1:1 ion association for each ion volume (purple dotted line), and for the cationic sandwich model (grey line).

In this case the simulated volume curves for the cation and anion (orange and green lines, respectively) were closer to the experimental data than the 1:1 ion pair association model. First indications were that cationic sandwich association provides indeed an excellent fit for both the conductivity as well as the DOSY NMR data.

3.1.4.5 Model IIb – Anionic Sandwich Association

Further comprehensive DOSY studies of all ion pair systems showed that the more nucleophilic ion pairs **4-6a** displayed results that indicated an anionic sandwich association rather than a cationic sandwich association (see SI of ref. [2]). Adjustment of the cationic sandwich association to incorporate an anion sandwich consisting of four ions, two anions **A** and two cations **C** which associate into a formally negative charged sandwich complex **ACA** with one free cation **C** left over (see Scheme 3.3).

Scheme 3.3: [Scheme S3]. General anionic sandwich association equilibrium for pyridinamide ion pairs.

The anion sandwich association constant was defined as $k_1/k_2 = K_{ACA}$ with $k_2 = 1$ being a fixed value. The limited molar ionic conductivities for the anion and cation were calculated according to eq. 3.4. The limited molar ionic conductivity λ_{ACA} of the anionic sandwich complex was treated as another variable. To find the global minimum for both the limited molar ionic conductivity λ_{ACA} and the anionic sandwich association constant K_{ACA} the same fitting process as described above for the cationic sandwich association model was followed. Since the sandwich complex is formally negatively charged, it is recommended to start the optimization process with $\delta_{ACA} = \delta_A$. The results are summarized in Table 3.7.

Table 3.7: [Table S7]. Anionic sandwich association constants K_{ACA} (M⁻²) with the specific molar conductivities Λ_m (S cm² mol⁻¹) and the scaling factors δ_i of all charged species for pyridinamide ion pairs.

Ion Pair	Λ_m (S cm ² mol ⁻¹)	$\delta_A / \delta_C / \delta_{ACA}$ (%)	K_{ACA} (M ⁻²)	RMSE
3d	56.0	40/60/-	—	—
3c	57.9	41/59/4	1.01×10^7	0.100
3b	80.3	28/72/47	4.65×10^6	0.105
3a	79.2	37/63/41	6.38×10^6	0.173
5a	73.2	42/58/41	5.15×10^6	0.130
4a	73.6	44/56/42	6.50×10^6	0.122
6a	74.2	45/55/50	6.75×10^6	0.161

Numerical simulation of both sandwich association types gave identical association constants and RMSE values. Thus, based on conductivity data alone, those two association types cannot be distinguished. The sole exception is ion pair **3d**. Here the global minimum could not be found in the anionic sandwich association without allowing negative values for the limited molar ionic conductivity λ_{ACA} . This indicates either that for this ion pair, an anionic sandwich association is not feasible or that model II ran into a numerical boundary. In both cases, no optimized anionic sandwich association constant K_{ACA} could be found for ion pair **3d**.

For the comparison of the experimental and simulated ion volumes, the simulated volumes were calculated according to eq. 3.8 for the anionic sandwich association model.

$$vol_{cat} = \left(\frac{[C]}{[IP]_{tot}} \right) \times 362 + \left(\frac{[ACA]}{[IP]_{tot}} \right) \times 782 \quad (3.8a)$$

$$vol_{an} = \left(\frac{[A]}{[IP]_{tot}} \right) \times 215 + \left(\frac{2 \times [ACA]}{[IP]_{tot}} \right) \times 782 \quad (3.8b)$$

The comparison showed that the anionic sandwich association model does not offer a better overlap between the experimentally obtained and simulated ion volumes. Figure 3.7 shows the simulated ion volumes for both the cationic and the anionic sandwich association model exemplary for pyridinamide ion pair **3a**.

Figure 3.7: [Figure S7]. Concentration-dependent volumes of cations **a** (orange “+” symbols) and anions **3** (green “-” symbols) of salt **3a** in CD_2Cl_2 as calculated from DOSY experiments (with data from ref. [2]) with the respective free ion volumes (dotted line; cation in orange; anion in green), the calculated trend for 1:1 ion association for each ion volume (purple dotted line), and for the cationic (grey line) and anionic (blue dashed line) sandwich model.

While the simulated cation volumes based on the cationic sandwich association model are larger than the experimental values, the simulated cation volumes based on the anionic sandwich association are smaller than them. For the simulated anion volumes, the opposite holds true. For pyridinamide ion pair **3a** the cationic sandwich model is preferred since the increase in anion volumes should be obvious in the DOSY measurements, with the anion volumes surpassing the cation volumes as it can be seen for pyridinamide ion pair **4a** (for further details see Chapter 2)

3.1.4.6 Model III – Mixed Sandwich Association

Since the separate analysis of the conductivity data for both cationic and anionic sandwich association still revealed significant deviations in comparing the experimental and simulated ion volumes, the combination of both sandwich association types in the *mixed sandwich association model* was the next step. Therefore, both sandwich association constants, K_{CAC} and K_{ACA} , were assigned a *scaling factor* α and β , respectively (see Scheme 3.4).

Scheme 3.4: [Scheme S4]. Association equations for mixed sandwich association model.

To find the right ratio between cationic and anionic sandwich association one contribution factor would be set to a fixed value, while the other one would be treated as a variable and be optimized by using numerical simulation to find the minimum of the RMSE value. The optimization of the contribution factor was limited to two relevant decimals.

Cation and anion volumes obtained by DOSY NMR measurements at 1.0 mM salt concentration were used as reference to determine the optimal ratio for the factors, α and β . The simulated ion volumes were calculated according to eq. 3.9.

$$\text{vol}_{\text{cat}} = \frac{[C]}{[IP]_{\text{tot}}} \times 362 + \left(\frac{2 \times [CAC]}{[IP]_{\text{tot}}} \right) \times 925 + \left(\frac{[ACA]}{[IP]_{\text{tot}}} \right) \times 782 \quad (3.9a)$$

$$\text{vol}_{\text{an}} = \frac{[A]}{[IP]_{\text{tot}}} \times 215 + \left(\frac{[CAC]}{[IP]_{\text{tot}}} \right) \times 925 + \left(\frac{2 \times [ACA]}{[IP]_{\text{tot}}} \right) \times 782 \quad (3.9b)$$

The percentual residual between experimental and simulated ion volumes determined the optimal ratio for the factors, α and β in the mixed sandwich association. For more details see Chapter 2

Examining the simulated ion volumes based on Model II for the cationic and anionic sandwich association against the newly introduced mixed model showed a significantly improved overlap for the experimental data than any other association model (see Figure 3.8, exemplary for ion pair **3a**).

Figure 3.8: [Figure S8]. Concentration-dependent volumes of cations **a** (orange “+” symbols) and anions **3** (green “-” symbols) of salt **3a** in CD₂Cl₂ as calculated from DOSY experiments (with data from ref. [2]) with the respective free ion volumes (dotted line; cation in orange; anion in green), the calculated trend for 1:1 ion association for each ion volume (purple dotted line), for the cationic (grey line) and anionic (blue dashed line) sandwich model and the mixed sandwich association model (brown short-dash line).

The mixed model gave the best results when checking the experimental and simulated ion volumes against each other. The results of model 3 for all ion pairs are summarized in Table 3.8.

Table 3.8: [Table S8]. Final cationic and anionic sandwich association constants K_{CAC} (M⁻²) and K_{ACA} (M⁻²) with the specific molar conductivities Λ_m (S cm² mol⁻¹) and the scaling factors δ_i of all charged species with their respective scaling factors α and β for pyridinamide ion pairs.

Ion Pair	Λ_m (S cm ² mol ⁻¹)	$\delta_A/\delta_C/\delta_{CAC}/\delta_{ACA}$	$\alpha \times K_{CAC}$ [M ⁻²]	$\beta \times K_{ACA}$ [M ⁻²]	α/β (%)	RMSE
3d	56.0	40/60/15/-	—	—	—	—
3c	57.9	41/59/22/4	3.33×10^6	2.32×10^6	33/23	0.61

3b	80.3	28/72/91/47	4.65×10^6	0.00	100/0	0.11
3a	79.2	37/63/67/41	2.81×10^6	1.34×10^6	44/21	0.43
5a	73.2	42/58/57/41	5.67×10^5	3.45×10^6	11/67	0.29
4a	73.6	44/56/54/42	7.80×10^5	3.97×10^6	12/61	0.35
6a	74.2	45/55/60/50	1.08×10^6	3.51×10^6	16/52	0.38

Notable is the result of the analysis of pyridinamide ion pair **3b** in the mixed model. For the **3b** the best result was achieved for the purely cationic sandwich association without any participation of the anionic sandwich association. However, the percentual residual for both cation and anion volume are rather large with +25% for the anion volume and +14% for the cation volume (see Figure 3.9A) compared to the results of the other ion pairs, e.g. $\pm 6.0\%$ for ion volume in pyridinamide ion pair **3a** (see Figure 3.9B).

Figure 3.9: [Figure S9]. A) Percentual residue for calculated cation (blue (for β fixed) and grey (for α fixed) “+”) and anion (blue (for β fixed) and grey (for α fixed) “–”) volumes in mixed sandwich association model for pyridinamide ion pair **3b**. B) Percentual residue for calculated cation (blue (for β fixed) and grey (for α fixed) “+”) and anion (blue (for β fixed) and grey (for α fixed) “–”) volumes in mixed sandwich association model for pyridinamide ion pair **3a**.

This might be an indication for other ionic species or ionic effects taking place in solution for **3b** that are not yet accounted for in the current conductivity model. Moving forward, pyridinamide ion pairs **3b** as well as **3d** will be analyzed with the cationic sandwich association model.

3.1.4.7 Workflow summary

For the determination of ion pairing constant K_{IP} and sandwich association constant K_{CAC} for ionic compounds like **3a** based on conductivity measurements in DCM, the following steps were carried out:

Determination of ion pairing constant K_{IP} (M^{-2}) for salt **3a**

- Measure conductivity for **3a**.
- Determine the molar conductivity Λ_m by linear extrapolation of the first three data points.
- Use eq. 3.3 or the respective biochemical model (for details see Scheme 3.1 or 3.2) concentrations for all compound involved in the model, copy the concentrations into excel to convert them into conductivity values by assigning both ion 50% contribution towards Λ_m .
- Compare sum of theoretical conductivity with experimental values (without solvent background conductivity).
- Use the RMSE value as a quality control measure.
- Adjust k_1 in $K_{CAC} = k_1/k_2$ until the minimum RMSE is found, to obtain K_{IP} .

Determination of sandwich association constant K_{CAC} (M^{-2}) for salt **3a**

- Measure conductivity for **3a**.
- Determine the molar conductivity Λ_m by linear extrapolation of the first three data points.

- i) Set the limited molar ionic conductivity for the anion λ_A and cation λ_C to the calculated values for the scaling factor δ_i based on eq. 3.8. The sum of $\delta_A + \delta_C$ cannot exceed 1.
- j) Treat $\delta_{CAC} = \lambda_{CAC}/\Lambda_m(\mathbf{3a})$ as a second variable. Select a starting value e.g. $\delta_{CAC} = 0.67$ and start the optimization process for K_{CAC} .
- k) Use the respective sandwich association model (Model 3) to obtain concentrations for all species involved, copy them into Excel to convert them into conductivity values using eq. 3.5.
- l) Compare sum of theoretical conductivity with experimental values (without solvent background conductivity).
- m) Use the RMSE values as a quality control measure.
- n) Adjust k_1 in $K_{CAC} = k_1/k_2$ until minimum RMSE is found, to obtain the final K_{CAC} .
- o) Adjust the limited molar ionic conductivity for the sandwich ion λ_{CAC} to find the percentual distribution that fits the conductivity data the best. For each new percentual distribution, repeat step k) – n) until the global minimum RMSE is found.

For analysis of the additive **7a-d** the same steps are followed, only step q deviates since the determination of the specific molar conductivity Λ_m of BF_4^- is done slightly differently:

- p) Measure conductivity for salt **7a-d**.
- q) Determine the molar conductivity Λ_m by linear extrapolation of the first three data points.
- r) Follow step i) – o) as described above to obtain K_{CAC} for additive **7a-d**.

Determination of composition of cationic and anionic sandwich association for salt **3a** (Model 3)

After determination of the cationic sandwich association constant K_{CAC} and the anionic sandwich association K_{ACA} the mix of both association types that fits the experimental data best is ascertained.

- s) Assign each association constant a *scaling factor*: $K_{CAC} \times \alpha$ and $K_{ACA} \times \beta$.
- t) Set α to a fixed value starting at 1.0 and going down in steps of 0.1. Optimize β to achieve the smallest RMSE value for the conductivity data using numerical simulations. Limit each factor to two relevant decimals.
- u) Repeat step s) vice versa for factor β .
- v) Determine the composition of cationic and anionic sandwich association in reference to the measured DOSY volume at 1.0 mM by calculating the percentual residual between experimental and simulated ion volumes.
- w) Take further optimization steps until finding the α/β ratio with the smallest percentual residual for both cation and anion volume.

3.1.5 Nucleophilicity Data

The reaction rates of ion pair catalysts and TCAP (**2**) and the reference electrophiles were measured photometrically on a stop-flow spectrophotometer. The temperature was controlled with a circulating bath thermostat. The kinetic reactions were carried out under pseudo-first-order conditions (ion pair = nucleophile, excess compound) at the absorption maximum of benzhydrylium ion in the respective solvent as described previously by the H. Mayr group.^[10] First-order rate constants k_{obs} (s^{-1}) were derived by fitting the absorbance according to the mono-exponential curve $A_t = A_0 \exp(-k_{\text{obs}} t) + C$ (see Figure 3.10).

Figure 3.10: [Figure S11]. Absorbance decay of benzhydrylium salt **8a** reacting with nucleophile TCAP (**2**) in DCM at 20°C, fitted by mono-exponential decay function resulting in $k_{\text{obs}} = 1.19 \text{ s}^{-1}$.

Then the second-order rate constant k_2 ($\text{L mol}^{-1} \text{ s}^{-1}$) is obtained from the slope of the linear plots of k_{obs} (s^{-1}) vs $[\text{Nu}]$ since $k_{\text{obs}} = k_2[\text{Nu}]$. The subsequent characterization is based on the Mayr-Patz eq. 3.10 where the reaction rates for the reaction of the nucleophile with the electrophile is expressed as a function of the nucleophilicity parameter N , the associated sensitivity parameter s_N , and the electrophilicity parameter E . Both, N parameter and nucleophile-specific s_N parameter are solvent dependent.^[10–12]

$$\log k_2^{20^\circ\text{C}} = s_N(N + E) \quad (3.10)$$

3.1.5.1 Kinetic Data Analysis

Measurements of ionic compounds performed in non-polar solvents require more consideration due to the influence of ion association on the first-order rate constant k_{obs} . To negate the effect of ion association in solution, the ionic strength controlled benzhydrylium method was developed where a non-nucleophilic, structurally related salt was added as additive to keep ionic strength I constant throughout the kinetic.

Kinetic data gathered under conditions of ionic strength control $I = 1.0 \text{ mM}$, can be analyzed in multiple ways (for full discussion see Chapter 2). The most practical way would be to assume that the amount of weighted salt equals the amount of nucleophile in solution. Here, the standard Mayr method would be employed to obtain the second-order rate constant k_2 and subsequently gain the N parameter and s_N parameter.

The combination of conductivity and DOSY NMR, however, revealed a complex ion association taking place in solution, where the single ions associate into distinctive triple ion complexes of the type, **CAC**, and **ACA**. It is assumed that the remaining free anion **A** is the only reactive nucleophile in solution. To determine the concentration of free nucleophile **A** in solution, the conductivity model III was used as basis. Since the association of the pyridinamide ion pair is controlled *via* the addition of the additive salt, the association of the additive itself has to be considered. The existing model III was extended by adding the association equation for the additive to it (see Scheme 3.5).

Scheme 3.5: [Scheme S5]. Numerical simulation equations of mixed sandwich association model extension for evaluation of ionic strength controlled kinetic data.

Since there are two pyridinamide ion pairs, **3b** and **3d**, whose association pattern could not be analyzed with the mixed sandwich association model, an alternative extension for the nucleophilicity data evaluation will be included here. DOSY NMR data revealed the cationic sandwich association as a suitable association model for pyridinamide ion pairs with the deprotonated 1,1,1-trifluoro-*N*-(pyridin-4(1*H*)-ylidene)methanesulfonamide as anion (see ref. [2]). As an alternative, model IIa was used as basis for another extension for the analysis of the ionic strength-controlled benzhydrylium method (see Scheme 3.6).

Scheme 3.6: [Scheme S6]. Numerical simulation equations of cationic sandwich association model extension for evaluation of ionic strength controlled kinetic data.

Now, both models were used to evaluate the gathered kinetic data. For completeness, all kinetic data sets were analyzed utilizing both association extensions to obtain the respective nucleophilicity parameters *N* and *s_N*. Numerical simulation to obtain the relevant ion concentrations were performed using COPASI, whereas the individual starting concentrations are defined as:

- [**A**] = concentration of pyridinamide salt
- [**C**] = concentration of pyridinamide salt + concentration of additive
- [**B**] = concentration of additive + concentration of the respective benzhydrylium salt.

The resulting *N*- and *s_N*-parameter of the ionic-strength controlled benzhydrylium method for pyridinamide ion pairs in DCM are summarized in Table 3.9. The applied models are distinguished by superscripts: “HC” = [**A**]_{tot} with *I* = 1.0 mM, “HC,sw” = [**A**] obtained by model IIa extension with *I* = 1.0 mM, and “HC,mix” = [**A**] obtained by model III extension with *I* = 1.0 mM.

Table 3.9: [Table S14]. List of *N*- and *s_N*-parameter obtained with different evaluation models for pyridinamide ion pairs in DCM.

3.1.5.5 Effects of Ion Association on Nucleophilicity Measurements

The so-called wide range measurements employ the same principle as the benzhydrylium kinetics except for covering a much larger concentration range (1×10^{-5} to 4×10^{-3}). The aim of these measurement to illustrate the influence of ion pair formation with increasing concentration on the first-order reaction rate k_{obs} (s^{-1}) and obtained second order rate constants k_2 ($\text{M}^{-1} \text{s}^{-1}$) are generally not included in the N and s_N parameter determination. The benzhydrylium salt $(\text{lil})_2\text{CH}^+\text{BF}_4^-$ (**8a**) was used as electrophile at $\lambda = 640 \text{ nm}$.

Measurement of **3b** at 20°C

Reaction of **3b** with $(\text{lil})_2\text{CH}^+\text{BF}_4^-$ in DCM (stopped-flow, $\lambda = 640 \text{ nm}$)

3.1.6 pK_a Measurements

3.1.6.1 General information – pK_a measurements in aqueous solutions

The neutral pyridinamides as well as the respective ion pairs were stored under nitrogen atmosphere. Hygroscopic salts were dried *in vacuo* for 12 h prior to being used in the buffer preparation. Pure water was used for the preparation of buffer solutions and stock solutions. For pipetting the buffer and stock solutions *Eppendorf* pipettes were used. All calibration solutions and the baseline solutions were tempered at 25 °C using a circulating water bath.

UV-Vis Spectra were recorded on a Varian Cary 100 Bio Spectrophotometer (version 9.00) maintained at 25 °C using the “scan software” (version 3.00(182)) and the “kinetics software” (version 3.00(182)). The scan software was used to record the full UV-Vis spectrum of the respective compound between 200 - 400 nm, while the kinetics software was used to validate the stability of the compound at a fixed wavelength, whereas the absorbance was measured every 0.1 min for 1.0 min. Before starting the measurement, the respective wavelength was selected, and the instrument was “zeroed” to air. The baseline function of the program was not used. Instead, a baseline spectrum would be measured for each data point where the solution had the same composition as the actual measurement but without the compound in it. The baseline spectrum was then subtracted from the measurement spectrum using Excel. The pH value of each baseline mixture was determined using a Radiometer Analytical RadioLab pH 210 standard pH meter connected to a radiometer electrode filled with saturated KCl solution. The electrode was stored in 3.0 M KCl solution in between measurements. Calibration of the setup was done at intervals of $pH = 1.4 - 4.0$, $4.0 - 7.0$, and $7.0 - 10.0$ shortly before measuring the respective baseline mixtures, which were tempered to 25 °C using a circulating water bath for at least 30 min prior to measuring.

For the aqueous pK_a measurements the neutral pyridinamides were dissolved in premixed MeCN/pure water mixtures (ratio = 50/50 of volume) and added to aqueous buffer solutions ($c = 0.05$ M or 0.1 M, $I = 0.3$ M) to give measurement solutions with a compound concentration of $c = 0.05$ mM. The absorbance of the neutral pyridinamide or respective anion was measured across the pH range and the resulting absorbance- pH plots were fitted using Origin. To obtain the necessary equation for the fitting, equations 3.11-3.15 are used, with eq. 3.12-3.14 being inserted into eq. 3.11 to give eq. 3.15 with K_a being the acid dissociation constant for the compound, pH is the one of the used buffers, A_{obs} being the observed absorbance, A_{max} the maximum absorbance (where the compound is either protonated or deprotonated) and A_{min} is the minimum absorbance (where the compound is either fully protonated or fully deprotonated).

When the chosen wavelength is following the neutral pyridinamide, e.g. 285 nm for pyridinamide **5**, the absorbance is increasing with the pH ($pH < 6$), thus A_{max} reflects the neutral pyridinamide (one proton at the pyridine nitrogen) and A_{min} the fully protonated pyridinamide form, which is depicted in eq. 3.13 and eq. 3.14.

$$K_a = \frac{[H^+][A^-]}{[HA]} \quad (3.11)$$

$$[H^+] = 10^{-pH} \quad (3.12)$$

$$[A^-] = A_{obs} - A_{min} \quad (3.13)$$

$$[HA] = A_{max} - A_{obs} \quad (3.14)$$

$$K_a = \frac{10^{-pH}(A_{\text{obs}} - A_{\text{min}})}{(A_{\text{max}} - A_{\text{obs}})} \quad (3.15)$$

Increase in absorbance:
$$A_{\text{obs}} = \frac{10^{-pH} \times A_{\text{min}} + K_a \times A_{\text{max}}}{10^{-pH} \times K_a} \quad (3.16)$$

When further increasing pH ($pH > 6$) the absorbance of the neutral pyridinamide decreases due to deprotonation of the neutral pyridinamide towards the fully deprotonated anion. Here, A_{max} reflects the neutral pyridinamide and A_{min} the fully deprotonated anion. Therefore, eq. 3.13 and 3.14 are rewritten into eq. 3.17 and eq. 3.18. Inserting those equations into eq. 3.11 and solving it for A_{obs} results in eq. 3.19 with which the decrease in absorbance can be fitted in Origin to obtain K_a . In Origin A_{max} and A_{min} are treated as variables.

$$[A^-] = A_{\text{max}} - A_{\text{obs}} \quad (3.17)$$

$$[HA] = A_{\text{obs}} - A_{\text{min}} \quad (3.18)$$

Decrease in absorbance:
$$A_{\text{obs}} = \frac{10^{-pH} \times A_{\text{max}} + K_a \times A_{\text{min}}}{K_a + 10^{-pH}} \quad (3.19)$$

Taking the logarithm of K_a (see eq. 3.20) gives the final value for pK_a .

$$pK_a = -\log_{10} K_a \quad (3.20)$$

Preparation of buffer solutions

The buffer solutions are prepared according to the Henderson-Hasselbalch equation (see eq. 3.21). Several acid-base pairs with varying amounts of free base were chosen to obtain the wanted pH value in the final buffer solution (see Table 3.10).

$$pH = pK_a + \log \frac{A^-}{HA} \quad (3.21)$$

The ionic strength I of the buffer solution is calculated according to eq. 3.22 with c_i being the concentration of ions in solution and z_i^2 the charge of ions squared.

$$I = \frac{1}{2} \sum c_i z_i^2 \quad (3.22)$$

For comparable results, all buffer solutions must have to the same ionic strength I independent of the concentration and composition regarding the acid and base of the final buffer solutions.

All prepared buffer solutions for the aqueous pH -titration with their acid-base pairs, amount of free base (fb) and measured pH value are listed below. All buffer solutions are prepared to have a concentration of 0.1 M and an ionic strength I of 0.3 M which is achieved by addition of potassium chloride (KCl).

Table 3.10: [Table S15]. List of prepared aqueous buffer solution with the involved acid and bases, the pK_a value of the respective acid, the amount of free base (fb) in percentage, the final buffer concentration, and the resulting pH

Pyridinamide ion pair **5a** – aqueous pK_a

Stock solution prepared using pyridinamide ion pair **5a** rather than pyridinamide **5** to examine the potential influence of the counter-cation **a** on the measurement. The measurement was performed following two wavelengths: at 285 nm for the pyridinamide and at 258 nm for the pyridinamide anion **5**.

VB25. Stock solution A with 5.89 mg **5a** in 10 mL H₂O/MeCN mix (1:1), diluted to $c = 0.05$ mM, measured at $\lambda_{\max}(\text{PA}_5) = 285$ nm and $\lambda_{\max}(\text{5a}) = 258$ nm.

3.1.6.2 General information – pK_a measurements in MeCN mixtures

The respective ion pairs **3-6a** were used for stock solutions due to solubility issues of the pyridinamides for the pK_a determination in water/MeCN mixtures with a ratio of 50/50. Stock solution A with $c = 1.0$ mM of the respective neutral pyridinamides in MeCN was prepared and diluted with MeCN to give stock solution B with $c = 0.1$ mM. Subsequently, 0.5 mL of stock solution B was combined with 0.5 mL of buffer solution to give the final measurement mixture with a compound concentration of $c = 0.05$ mM.

However, due to dilution the final ionic strength of the measurement solution was reduced to $I = 0.15$ M. To verify that the reduced ionic strength would not influence the final pK_a value a test measurement with neutral pyridinamide PA_3 was performed with the same conditions as for the aqueous pK_a measurement with the exception that the stock solution was diluted in a way that the ionic strength of the measurement mixture would be $I = 0.15$ M. The resulting pK_a value of this measurement did not deviate from the pK_a value obtained with $I = 0.3$ M. To the observed pH_{obs} of the water/MeCN mixtures a correction factor δ_{MeCN} must be applied since the pH_{obs} was determined with an electrode calibrated in

aqueous solutions. Therefore, a correction of -0.257 was added to the measured output of the pH probe.^[14]

DMAP – pK_a in MeCN mixture

3.1.6.3 General information – pK_a measurements in DMSO mixtures

Stock solution A with $c = 1.0$ mM of the respective neutral pyridinamides in DMSO was prepared and diluted with DMSO to give stock solution B with $c = 0.1$ mM. 0.5 mL of stock solution B was combined with 0.5 mL of buffer solution to give the final measurement mixture with a compound concentration of $c = 0.05$ mM. In this chapter only observed pH values are reported for the deprotonation of the neutral pyridinamide to the fully deprotonated anion.

Pyridinamide 3 – pK_a in DMSO

VB31. Stock solution A with 2.29 mg PA_3 in 10 mL DMSO, diluted to $c = 0.05$ mM, measured at $\lambda_{\text{max}} = 275$ nm.

	80	8.96	8.75	1.00

Figure 1 consists of two plots. Plot (a) shows the absorbance (Abs) of the 100 mg/L solution as a function of pH. The x-axis ranges from 0 to 14, and the y-axis ranges from 0.0 to 1.8. The data points show a sharp decrease in absorbance between pH 6 and pH 10, leveling off around pH 11. Plot (b) shows the absorbance (Abs) of the 100 mg/L solution as a function of wavelength (nm) for various pH values. The x-axis ranges from 220 to 320 nm, and the y-axis ranges from 0.0 to 1.8. The curves show a shift in the absorption peak from approximately 260 nm at pH 5.9 to 285 nm at pH 11.46.

Chemical reaction scheme showing the equilibrium between PA 4 and an4. The reaction is catalyzed by In H₂O/DMSO (50/50) at 25 °C.

PA 4 (left) is a pyridine ring with a 4-methoxyphenylsulfonyl group at the 2-position. The reaction is catalyzed by In H₂O/DMSO (50/50) at 25 °C. The product, an4 (right), is the anionic form of PA 4, where the nitrogen atom of the pyridine ring carries a negative charge and the sulfonyl group is deprotonated.

Figure 1 consists of two plots. Plot (a) shows Absorbance (Abs.) on the y-axis (0.0 to 1.8) versus pH on the x-axis (0 to 14). The data points show a sigmoidal decrease in absorbance as pH increases, starting around pH 6 and leveling off around pH 12. Plot (b) shows Absorbance (Abs.) on the y-axis (0.0 to 1.8) versus wavelength (nm) on the x-axis (220 to 320). Multiple curves are shown for different pH values: 5.9, 6.75, 7, 7.54, 7.9, 8.51, 8.75, 11.79, 12.25, 12.63, and 13.46. The curves show a shift in the main absorbance peak from approximately 260 nm at low pH to approximately 290 nm at high pH.

$$pK_a = 8.57$$

3.1.7 NMR Kinetics

The urethane synthesis was chosen as benchmark reaction to insert the newly designed ion pair catalyst into to existing reactivity library and compare their reactivity with already known ion pair catalysts. The benchmark reaction was performed with pyridinamide ion pair **3a**, **3b**, **5a**, and **6a**. The effective rate constants for **3c** and **4a** were taken from Helberg and Zipse.^[3]

The reactant *p*-tosyl isocyanate (**9**, reagent grade) was distilled prior to use. The reactant 1-butanol (**10**, reagent grade) was distilled and stored over 4Å MS and under N₂ prior to use.

Scheme 3.7: [Scheme S7]. Urethane synthesis with *p*-tosyl isocyanate (**9**) and 1-butanol (**10**) giving urethane **11**.

The experimental procedure and evaluation of the urethane synthesis was done as described as in Helberg and Zipse.^[3] There the conversion was calculated according to eq. 3.23.

$$\text{Conversion [\%]} = \frac{3 \times \text{product}(\text{CH}_2)}{2 \times (\text{prod}(\text{me}) + \text{isocyanat}(\text{Me}))} \times 100 \quad (3.23)$$

The conversion is then used to calculate the concentration of urethane at the time t $c_t[\text{product}]$ based on the initial concentration c_0 (eq. 3.24).

$$c_t = c(\mathbf{9})_0 - \left(\frac{c(\mathbf{9})_0 \times (100 - \text{conversion})}{100} \right) \quad (3.24)$$

Numerical simulation according to eq. 3.25 were performed using the program COPASI to obtain the respective effective rate constants k_{eff} .

$$[\mathbf{9}] + [\mathbf{10}] = [\text{urethane } \mathbf{11}] \quad (3.25)$$

The benchmark reaction was performed with three different catalyst loadings and in two independent runs each. The resulting averaged effective rate constants k_{eff} are summarized in Table 3.11.

Table 3.11: [Table S16]. List of averaged k_{eff} values obtained for the urethane synthesis with 1.0 mol%, 3.0 mol%, and 6.0 mol% catalyst loading.

IP	$k_{\text{eff}}(\mathbf{1}) / \text{M}^{-1} \text{s}^{-1}$	$k_{\text{eff}}(\mathbf{3}) / \text{M}^{-1} \text{s}^{-1}$	$k_{\text{eff}}(\mathbf{6}) / \text{M}^{-1} \text{s}^{-1}$	$k_{\text{cat}} / \text{M}^{-2} \text{s}^{-1}$
1 ^[a]	—	2.80×10^{-4}	—	0.086
2 ^[a]	2.78×10^{-4}	7.50×10^{-4}	—	0.364
3a	$2.26 \times 10^{-4} \pm 3.67 \times 10^{-6}$	$6.01 \times 10^{-4} \pm 1.50 \times 10^{-6}$	$1.20 \times 10^{-3} \pm 2.19 \times 10^{-5}$	0.196
3b	$2.45 \times 10^{-4} \pm 1.86 \times 10^{-6}$	$7.15 \times 10^{-4} \pm 1.56 \times 10^{-5}$	$1.27 \times 10^{-3} \pm 1.61 \times 10^{-5}$	0.205
3c ^[a]	—	3.65×10^{-4}	—	0.115
4a ^[a]	8.04×10^{-4} ^[b]	1.99×10^{-3}	3.96×10^{-3}	0.661
5a	$5.28 \times 10^{-4} \pm 1.95 \times 10^{-6}$	$1.53 \times 10^{-3} \pm 8.03 \times 10^{-6}$	$2.90 \times 10^{-3} \pm 1.20 \times 10^{-4}$	0.477
6a	$4.30 \times 10^{-4} \pm 3.14 \times 10^{-6}$	$1.25 \times 10^{-3} \pm 2.50 \times 10^{-6}$	$2.58 \times 10^{-3} \pm 4.34 \times 10^{-5}$	0.433

[a] values taken from ref. [3]. [b] measured with 1.2 mol% catalyst load.

Subsequently the effective rate constants can be used to determine the concentration-independent rate constant of each catalyst according to eq. 3.26.

$$k_{\text{eff}} = k_{\text{cat}} \times [\text{catalyst}] \quad (3.26)$$

Plotting the effective rate constant k_{eff} against the respective catalyst load [catalyst] reveals a clear linear correlation for all investigated systems with a very small Y-intercept, thus, indicating that any potential uncatalyzed background reaction is negligible.

Figure 3.11: [Figure S12]. Correlation of catalytic activity at increasing catalyst loadings for the urethane synthesis with data from ref. [3] for **4a**.

The relative catalytic performance of the pyridinamide ion pair is reflected in the slope of the correlation as the concentration-independent rate constant k_{cat} ($\text{M}^{-2} \text{s}^{-1}$).

The fitted values of the effective rate constants k_{eff} by COPASI with a catalyst load of 3.0 mol% are summarized in Table 3.12.

Table 3.12: [Table S17]. List of k_{eff} values obtained for the urethane synthesis (3.0 mol%).

Catalyst	Run	Yield [%]	k_{eff}	Average k_{eff}
3a	1	99	6.00×10^{-4}	$6.01 \times 10^{-4} \pm 1.50 \times 10^{-6}$
	2	99	6.03×10^{-4}	
3b	1	99	7.30×10^{-4}	$7.15 \times 10^{-4} \pm 1.56 \times 10^{-5}$
	2	99	6.99×10^{-4}	
5a	1	98	1.54×10^{-3}	$1.53 \times 10^{-3} \pm 8.03 \times 10^{-6}$
	2	98	1.52×10^{-3}

The absolute kinetics of the urethane reaction were done with 6.0 mol% catalyst. The results are summarized in Table 3.17.

Table 3.17: [Table S22]. List of k_{eff} values obtained for the urethane synthesis (6.0 mol%).

Catalyst	Run	Yield [%]	k_{eff}	Average k_{eff}
3a	1	99	1.17×10^{-3}	$1.20 \times 10^{-3} \pm 2.19 \times 10^{-5}$
	2	99	1.22×10^{-3}	
3b	1	99	1.25×10^{-3}	$1.27 \times 10^{-3} \pm 1.61 \times 10^{-5}$
	2	99	1.29×10^{-3}	
5a	1	94	2.78×10^{-3}	$2.90 \times 10^{-3} \pm 1.20 \times 10^{-4}$
	2	94	3.02×10^{-3}	
6a	1	99	2.62×10^{-3}	$2.58 \times 10^{-3} \pm 4.34 \times 10^{-5}$
	2	99	2.53×10^{-3}	

The raw data of absolute kinetics with 6.0 mol% catalyst are summarized in Table 3.18 to Table 3.21.

Table 3.18: [Table S23]. Raw data of absolute kinetic of urethane synthesis with 5a (6.0 mol%) in CDCl_3 .

The absolute kinetics of the urethane reaction were done with 1.0 mol% catalyst. The results are summarized in Table 3.22.

Table 3.22: [Table S27]. List of k_{eff} values obtained for the urethane synthesis (1.0 mol%).

Catalyst	Run	Yield [%]	k_{eff}	Average k_{eff}
3a	1	99	2.23×10^{-4}	$2.26 \times 10^{-4} \pm 3.67 \times 10^{-6}$
	2	99	2.30×10^{-4}	
3b	1	99	2.43×10^{-4}	$2.45 \times 10^{-4} \pm 1.86 \times 10^{-6}$
	2	99	2.47×10^{-4}	
5a	1	97	5.26×10^{-4}	$5.28 \times 10^{-4} \pm 1.95 \times 10^{-6}$
	2	98	5.30×10^{-4}	
6a	1	98	4.33×10^{-4}	$4.30 \times 10^{-4} \pm 3.14 \times 10^{-6}$
	2	98	4.27×10^{-4}	

The raw data of absolute kinetics with 1.0 mol% catalyst is summarized in Table 3.23 to Table 3.26.

Table 3.23: [Table S28]. Raw data of absolute kinetic of urethane synthesis with 5a (1.0 mol%) in CDCl_3 .

The X-ray crystal structure of compound **7a** has previously been reported (without the DCM solvate).^[15–17]

3.1.9 NMR Spectra

The recorded NMR spectra of compounds PA_3, PA_4, PA_5, 3c, 3d, and 4a were identical to the ones published in ref. [3].

N-(pyridin-4(1*H*)-ylidene)-4-(trifluoromethyl)benzenesulfonamide (6)

Triphenyl ((triphenyl-λ⁵-phosphaneylidene)amino) phosphonium pyridin-4-yl (trifluoromethyl) sulfonyl
 amide (**3b**)

Tetraphenylphosphonium pyridin-4-yl(tosyl)amide (**5a**)

Triphenyl((triphenyl- λ 5-phosphaneylidene)amino)phosphonium tetrafluoroborate (**7b**)

Tetrabutylammonium tetrafluoroborate (7c)

Tetrabutylphosphonium tetrafluoroborate (**7d**)

3.1.10 Computational Studies

All substrate structures were optimized with the B3LYP-D3 hybrid functional^[18–20] with the 6-31+G(d) basis set.^[21] Solvent effects for dichloromethane have been calculated with the SMD continuum solvation model.^[22] This combination has worked well in previous studies of charge-separated intermediates.^[23–26] Frequency and single point calculations were performed at the same level of theory. Thermochemical correction to 198.15 K has been applied to all found minima from unscaled vibrational frequencies obtained at the same level of theory. To lessen the impact of low-lying frequencies of large systems on entropy and enthalpy in an unpredictable manner, a free-rotor approximation for entropy as proposed by Grimme^[27] and a quasi-harmonic treatment with a cutoff value of 100 cm⁻¹ using Goodvibes^[28] was applied. Free energies in solution have been corrected to the reference state of 1.0 mol L⁻¹ at 298.15 K by adding 7.925 kJ mol⁻¹ to the free energies ($G_{298, \text{qh, corr}}$). All reported calculations were done with Gaussian 16, Revision A.03^[29] and B.01^[30].

The conformational search was performed with Maestro. For ion pair and additive salt systems, a set of 150 starting points was obtained by using the stochastic kick procedure invented by Saunders^[32] and further developed by Sakic.^[33] At a time, a set of 50 starting points was generated by a combination of the best, the second-best conformer, and the third-best conformer of the prior separately optimized anion and cation. In case on ion does not have more than two anion conformers, the last 50 starting points were obtained from the combination of the best anion conformer with the third best cation conformer. The following kick settings were used: Distance parameter: 3 Å, Minimal Distance 1.5 Å, Number of Fragments: 1, Number of Files: 50.

Starting points for the conformers of the ion pair systems were obtained from Julian Helberg. Conformers for the new systems with tetraphenyl phosphonium as cation (**3-6a**) were obtained by manual modification of the corresponding triphenyl methyl phosphonium containing systems, initially calculated by Helberg^[3], whereby the methyl group was replaced by a phenyl group. The starting point of ion pair **6a** were obtained by manual modification of the starting points of ion pair **5a** whereas the methyl group was manually fluorinated. Starting points for the *n*-butyl chained cations were generated by manually extending the methylated ion conformers of Julian Helberg. To represent tetraalkyl ammonium and tetraalkyl phosphonium cations (present in substrates **3c** and **3d**) without having to cover the entire conformational spaces of these largely flexible systems, the alkyl chains were restricted to their fully elongated, trans oriented state.

Starting points for the conformers of the sandwich cation and sandwich anion were obtained by sorting the optimized structures of the respective ion pair according to the total energy. The best six conformers were chosen and in combination with the best cation conformer the stochastic kick procedure invented by Saunders^[32] and further developed by Sakic^[33] was applied to generate 60 new substrate structures in total. The following kick settings were used: Distance parameter: 3 Å, Minimal Distance 1.5 Å, Number of Fragments: 1, Number of Files: 10.

The goal in calculating the respective triple ion conformers was to obtain the volumes based on the van der Waals cavities employed in the SMD continuum solvation model at the SMD(DCM)/B3LYP-D3/6-31+G(d) level of theory for the calculation of the volumes of ions based on the simulated concentrations in each respective conductivity model to compare the DOSY results with the results of the numerical simulations. Due to the heavy nature of the calculated systems (between 81 – 119 atoms) the less costly *r*²SCAN-3c developed by Grimme^[34] with Orca 5.0.3^[35] was used for pre-optimizations, followed by single point calculations at the SMD(DCM)/B3LYP-D3/6-31+G(d) level of theory with Gaussian 16, Revision C.01^[36].

The calculated ion volumes based on the van der Waals cavities employed in the SMD continuum solvation model at the SMD(DCM)/B3LYP-D3/6-31+G(d) level of theory with Gaussian 16 were used in the conductivity analysis (see Chapter 2.1.4 and Chapter 3.1.4). The calculated ion volumes of all computed species are summarized in Table 3.31.

Table 3.31: [Table S36]. Calculated isotropic polarizabilities and ion volumes for cations, anions, and ion aggregates based on the van der Waals cavity used in the SMD solvation model at the SMD(DCM)/B3LYP-D3/6-31+G(d) level of theory.

Calculating the volume of the ion pair by summing up the respective single cation and anion volumes and comparing it to the computed ion pair volume, we check if there is a problem regarding the additivity of these ions. The results are listed in Table 3.32.

Table 3.32: [Table S37]. Additivity analysis of ion aggregate volumes relative to the constituent ions based on SMD cavities calculated at the SMD(DCM)/B3LYP-D3/6-31+G(d) level of theory.

[a] Volume difference = Calculated volume - Sum of constituent volumes.

Comparing calculated volumes with the sum of constituent ion volumes of a charged species show comparably low deviations. Therefore, the additivity for the ion volumes is given.

Another property we looked at is the isotropic polarizability ions at the SMD(DCM)/B3LYP-D3/6-31+G(d) level of theory which is given in Bohr³ in the output file using Gaussian 16. With 1 Bohr = 0.529177 Å, we can convert these values to Å³ by multiplying with (0.529177)³ = 0.14818. The obtained isotropic polarizability values are summarized in Table 3.31 and correlated with the respective ion volumes in Figure 3.12.

Figure 3.12: [Figure S13]. Correlation of calculated ion volumes (Å³) vs. isotropic polarizability (Å³) for all calculated single anions (green dots) and cations (orange dots), ion pairs (purple dots), cationic and anionic sandwich complexes (grey and blue dots).

Plotting the ion volumes vs. the isotropic polarizability gives a strong correlation which is remarkable considering the various type of species involved in this data set.

So far, the cation size seems to be a key factor regarding the final association pattern of the ion pair. To check whether the ion size is correlating with another association parameter, we calculated the mol fraction $\alpha/(\alpha+\beta)$ for the scaling factor α of the cationic sandwich association in the mixed model. The results are listed in Table 3.33. Additionally, we calculated the volume difference Δvolume (\AA^3) between the cation and anion volumes.

Table 3.33: [Table S38]. List of cation volumes (\AA^3).

Ion aggregate	Constituent cation(s)	Volume cation (\AA^3)	Constituent anion(s)	α/β	$\alpha/(\alpha+\beta)$	Volume anion (\AA^3)	Volume difference ^[a]
3a	a_PPh4	362	3	44/21	0.68	215	147
3b	b_PNP	559	3	100/0	1.00	215	344
3c	c_NBu4	313	3	33/23	0.59	215	98.0
4a	a_PPh4	362	4	12/61	0.16	285	77.0
5a	a_PPh4	362	5	11/67	0.14	266	96.0
6a	a_PPh4	362	6	16/52	0.24	295	67.0

[a] Volume difference = cation volume - anion volume.

The mol fraction as well as the scaling factor α was plotted against the calculated volume difference Δvolume (\AA^3). Both graphs in Figure 3.13 show a strong correlation for ion pairs **3a**, **3b**, and **3c** where cation changes while the anion remains the same. There is no correlation when comparing ion pairs with changing anions and constant cation.

Figure 3.13: [Figure S14]. Left: correlation of scaling factor α with ion volume difference Δvolume (\AA^3). Right: correlation of mol fraction $\alpha/(\alpha+\beta)$ with ion volume difference Δvolume (\AA^3).

Assuming that other ion pairs such as **4a** would display a correlation with a similar slope when exchanging cation **a** (PPh_4^+) for cation **b** (PNP^+) we could predict the mol fraction for theoretical ion pair **4b** (see Figure 3.14).

Figure 3.14: [Figure S15]. Left: correlation of scaling factor α with ion volume difference Δvolume (\AA^3). Right: correlation of mol fraction $\alpha/(\alpha+\beta)$ with ion volume difference Δvolume (\AA^3).

Thus, ion pair **4b** would have a scaling factor α of 66 and a mol fraction of 0.49 if this assumption is correct, which would indicate a predominated cationic sandwich association.

3.1.10.1 Optimized Conformers of Pyridinamide Ion Pairs in DCM

System 3b – computational data

**Figure 3.15:** [Figure S16]. Ion association of pyridinamide ion pair **3b** and the single ions

The Boltzmann-averaged free reaction energy of the ion pairing of **3b** amounts to $\Delta G_{\text{qh},298,\text{corr}} = 1.3 \text{ kJ mol}^{-1}$ in DCM solution. Focusing only on the best conformers of the reactants and product the free reaction energy of the ion pairing of **3b** changes to $\Delta G_{\text{qh},298,\text{corr}} = -1.8 \text{ kJ mol}^{-1}$ in DCM solution. This result is mainly due to solvation effects since the gas phase free energy of the ion pairing amounts to $\Delta G_{\text{qh},298} = -213.4 \text{ kJ mol}^{-1}$. In addition, we note that the contribution of the D3-dispersion correction amounts to $\Delta E_{\text{disp}} = -67.0 \text{ kJ mol}^{-1}$ for the free energy in the DCM solution and in the gas phase. The blue marked cells show the Boltzmann-averaged values.

According to $\Delta G_{\text{qh},298,\text{corr}} = -RT \ln K$ and assuming $R = 8.314 \text{ J K}^{-1} \text{ mol}^{-1}$ and $T = 298.15 \text{ K}$, the respective equilibrium constant amounts to $K(\text{3b}, \text{DCM}) = +2.06$ for the best conformer of **3b** and to $K(\text{3b}, \text{DCM}) = +0.60$ for the Boltzmann-averaged free reaction energy. In this case the equilibrium constant K corresponds to the concentration of the reactants and products in the following way: $K = [\text{3b}]/[\text{3}][\text{b_PNP}] = [\text{3b}]/[\text{3}]^2$.

System 3c – computational data

Figure 3.17: [Figure S18]. Ion association of pyridinamide ion pair **3c** and the single ions.

The Boltzmann-averaged free reaction energy of the ion pairing of **3c** amounts to $\Delta G_{\text{qh},298,\text{corr}} = 7.3 \text{ kJ mol}^{-1}$ in DCM solution. Focusing only on the best conformers of the reactants and product the free reaction energy of the ion pairing of **3c** changes to $\Delta G_{\text{qh},298,\text{corr}} = +5.2 \text{ kJ mol}^{-1}$ in DCM solution. This result is mainly due to solvation effects since the gas phase free energy of the ion pairing amounts to $\Delta G_{\text{qh},298} = -243.8 \text{ kJ mol}^{-1}$. In addition, we note that the contribution of the D3-dispersion correction amounts to $\Delta E_{\text{disp}} = -50.0 \text{ kJ mol}^{-1}$ for the free energy in the DCM solution and in the gas phase. The blue marked cells show the Boltzmann-averaged values.

According to $\Delta G_{\text{qh},298,\text{corr}} = -RT \ln K$ and assuming $R = 8.314 \text{ J K}^{-1} \text{ mol}^{-1}$ and $T = 298.15 \text{ K}$, the respective equilibrium constant amounts to $K(\mathbf{3c}, \text{DCM}) = +0.12$ for the best conformer of **3c** and to $K(\mathbf{3c}, \text{DCM}) = +0.05$ for the Boltzmann-averaged free reaction energy. In this case the equilibrium constant K corresponds to the concentration of the reactants and products in the following way: $K = [\mathbf{3c}]/[\mathbf{3}] [\text{c_NBu4}] = [\mathbf{3c}]/[\mathbf{3}]^2$.

**Figure 3.18:** [Figure S19]. Structure of conformer cat3c_001 calculated at SMD(DCM)/ B3LYP-D3/6-31+G(d) level of theory

System 3d – computational data

**Figure 3.19:** [Figure S20]. Ion association of pyridinamide ion pair **3d** and the single ions.

The Boltzmann-averaged free reaction energy of the ion pairing of **3d** amounts to $\Delta G_{\text{qh},298,\text{corr}} = +1.1 \text{ kJ mol}^{-1}$ in DCM solution. Focusing only on the best conformers of the reactants and product the free reaction energy of the ion pairing of **3d** changes to $\Delta G_{\text{qh},298,\text{corr}} = +1.3 \text{ kJ mol}^{-1}$ in DCM solution. This result is mainly due to solvation effects since the gas phase free energy of the ion pairing amounts to $\Delta G_{\text{qh},298} = -250.4 \text{ kJ mol}^{-1}$. In addition, we note that the contribution of the D3-dispersion correction amounts to $\Delta E_{\text{disp}} = +176.3 \text{ kJ mol}^{-1}$ for the free energy in the DCM solution and in the gas phase. The blue marked cells show the Boltzmann-averaged values.

According to $\Delta G_{\text{qh},298,\text{corr}} = -RT \ln K$ and assuming $R = 8.314 \text{ J K}^{-1} \text{ mol}^{-1}$ and $T = 298.15 \text{ K}$, the respective equilibrium constant amounts to $K(\mathbf{3d}, \text{DCM}) = +0.59$ for the best conformer of **3d** and to $K(\mathbf{3d}, \text{DCM}) = +0.65$ for the Boltzmann-averaged free reaction energy. In this case the equilibrium constant K corresponds to the concentration of the reactants and products in the following way: $K = [\mathbf{3d}]/[\mathbf{3}] [\text{d_PBu4}] = [\mathbf{3d}]/[\mathbf{3}]^2$.

Table 3.38: [Table S43]. Energies for all systems shown in Figure 3.19.

**Figure 3.20:** [Figure S21]. structure of conformer cat3d_008 calculated at SMD(DCM)/ B3LYP-D3/6-31+G(d) level of theory.

System 5a – computational data

Figure 3.21: [Figure S22]. Ion association of pyridinamide ion pair **5a** and the single ions.

The Boltzmann-averaged free reaction energy of the ion pairing of **5a** amounts to $\Delta G_{\text{qh},298,\text{corr}} = -3.8 \text{ kJ mol}^{-1}$ in DCM solution. Focusing only on the best conformers of the reactants and product the free reaction energy of the ion pairing of **5a** changes to $\Delta G_{\text{qh},298,\text{corr}} = -4.8 \text{ kJ mol}^{-1}$ in DCM solution. This result is mainly due to solvation effects since the gas phase free energy of the ion pairing amounts to $\Delta G_{\text{qh},298} = -224.4 \text{ kJ mol}^{-1}$. In addition, we note that the contribution of the D3-dispersion correction amounts to $\Delta E_{\text{disp}} = +136.5 \text{ kJ mol}^{-1}$ for the free energy in the DCM solution and in the gas phase. The blue marked cells show the Boltzmann-averaged values.

According to $\Delta G_{\text{qh},298,\text{corr}} = -RT \ln K$ and assuming $R = 8.314 \text{ J K}^{-1} \text{ mol}^{-1}$ and $T = 298.15 \text{ K}$, the respective equilibrium constant amounts to $K(\mathbf{5a}, \text{DCM}) = +7.0$ for the best conformer of **5a** and to $K(\mathbf{5a}, \text{DCM}) = +4.5$ for the Boltzmann-averaged free reaction energy. In this case the equilibrium constant K corresponds to the concentration of the reactants and products in the following way: $K = [\mathbf{5a}]/[\mathbf{5}] [\mathbf{a_PPh4}] = [\mathbf{5a}]/[\mathbf{5}]^2$.

[a] using geometries optimized at SMD(DCM)/B3LYP-D3/6-31+G(d) level.

Figure 3.22: [Figure S23]. left: structure of conformer cat5a_012 calculated at SMD(DCM)/ B3LYP-D3/6-31+G(d) level of theory; right: crystal structure of one ion pair in catalyst 5a.

System 6a – computational data

Figure 3.23: [Figure S24]. Ion association of pyridinamide ion pair **6a** and the single ions.

The Boltzmann-averaged free reaction energy of the ion pairing of **6a** amounts to $\Delta G_{\text{qh},298,\text{corr}} = -3.8 \text{ kJ mol}^{-1}$ in DCM solution. Focusing only on the best conformers of the reactants and product the free reaction energy of the ion pairing of **6a** changes to $\Delta G_{\text{qh},298,\text{corr}} = -5.3 \text{ kJ mol}^{-1}$ in DCM solution. This result is mainly due to solvation effects since the gas phase free energy of the ion pairing amounts to $\Delta G_{\text{qh},298} = -216.2 \text{ kJ mol}^{-1}$. In addition, we note that the contribution of the D3-dispersion correction amounts to $\Delta E_{\text{disp}} = +115.8 \text{ kJ mol}^{-1}$ for the free energy in the DCM solution and in the gas phase. The blue marked cells show the Boltzmann-averaged values.

According to $\Delta G_{\text{qh},298,\text{corr}} = -RT \ln K$ and assuming $R = 8.314 \text{ J K}^{-1} \text{ mol}^{-1}$ and $T = 298.15 \text{ K}$, the respective equilibrium constant amounts to $K(\mathbf{6a}, \text{DCM}) = 8.5$ for the best conformer of **6a** and to $K(\mathbf{6a}, \text{DCM}) = 4.6$ for the Boltzmann-averaged free reaction energy. In this case the equilibrium constant K corresponds to the concentration of the reactants and products in the following way: $K = [\mathbf{6a}]/[\mathbf{6}] [\mathbf{a_PPh4}] = [\mathbf{6a}]/[\mathbf{6}]^2$.

Table 3.42: [Table S47]. Energies for all systems shown in Figure 3.23.

3.1.10.2 Calculations of Methyl Cation Affinity (MCA) values

A way to describe the Lewis basicity of organocatalysts is the calculation of methyl cation affinity value (ΔMCA). Therefore, the difference in free reaction energy is determined of the methyl transfer from pyridine ma_py to the more Lewis basic ion pair **3a-d,4-6a** forming the methylated pyridinamide Me_3a-d,4-6a according to the equations shown in Figure 3.25 to Figure 3.31.

Figure 3.25: [Figure S26]. Equation used for calculation of relative Lewis basicity of ion pair **3a** with pyridine as reference.

Δ MCA		-47.29		-47.33
all		-49.02		-49.29

Previous studies of Δ MCA indicate that the catalytic active center is situated on the pyridine N rather than the amide N. Since anion **6** is a newly designed compound Δ MCA were calculated for the pyridine N methylated and the amide N methylated conformer according to the equation shown in Figure 3.32. The energy values are listed in Table 3.51.

Figure 3.32: [Figure S33]. Comparison of MCA at pyridine-N position (N1) and amide-N position (N2) for anion **6** with pyridine as reference system.

The resulting Δ MCA show that the methylation on the pyridine N leads to the thermodynamic more stable product by 13.7 kJ mol⁻¹ in reaction enthalpy and by 16.6 kJ mol⁻¹ in the free reaction energy.

Table 3.51: [Table S56]. Energy for all systems shown in Figure 3.32.

3.1.10.3 Conformers of Pyridinamide Triple Ion Complexes in DCM

Starting points of pyridinamide ion triple complexes were pre-optimized using SMD(DCM)/ r^2 SCAN-3c level of theory with Orca 5.0.3^[35], followed by single point calculations at SMD(DCM)/B3LYP-D3/6-31+G(d) with Gaussian 16, Revision C.01^[36] to obtain calculated triple ion volumes based on the van der Waals cavities employed in the SMD continuum solvation model employed in Gaussian 16 so they are comparable to the calculated ion volumes of ion pair systems and the respective single cation and anions optimized at the SMD(DCM)/B3LYP-D3/6-31+G(d) with Gaussian 16.

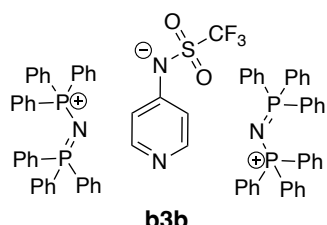

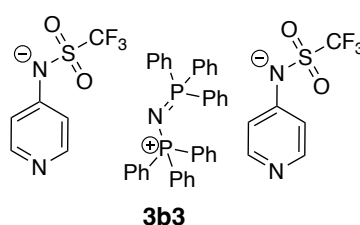

Table 3.52: [Table S57]. Single point energies for all triple ion systems of ion pair **3a** calculated at the SMD(DCM)/B3LYP-D3/6-31+G(d) level of theory with Gaussian 16

[a] best 20 conformers according to E_{tot} at SMD(DCM)/B3LYP-D3/6-31+G(d) level of theory.

3.1.10.4 Optimized Conformers of Additive Salts in DCM

System PNPBF₄ – computational data

Figure 3.33: [Figure S34]. Ion association of additive **7b** and the single ions.

The Boltzmann-averaged free reaction energy of the ion pairing of **7b** amounts to $\Delta G_{\text{qh},298,\text{corr}} = +13.9 \text{ kJ mol}^{-1}$ in DCM solution. Focusing only on the best conformers of the reactants and product the free reaction energy of the ion pairing of **7b** changes to $\Delta G_{\text{qh},298,\text{corr}} = +12.5 \text{ kJ mol}^{-1}$ in DCM solution. The blue marked cells show the Boltzmann-averaged values.

According to $\Delta G_{\text{qh},298,\text{corr}} = -RT \ln K$ and assuming $R = 8.314 \text{ J K}^{-1} \text{ mol}^{-1}$ and $T = 298.15 \text{ K}$, the respective equilibrium constant amounts to $K(\mathbf{7b}, \text{DCM}) = 0.007$ for the best conformer of **7b** and to $K(\mathbf{7b}, \text{DCM}) = 0.004$ for the Boltzmann-averaged free reaction energy. In this case the equilibrium constant K corresponds to the concentration of the reactants and products in the following way: $K = [\mathbf{7b}]/[\text{BF}_4] [\mathbf{b_PNP}] = [\mathbf{7b}]/[\text{BF}_4]^2$.

Table 3.59: [Table S64]. Energies for all systems shown in Figure 3.33.

[a] best 20 conformers according to $G_{qh,298}$ at SMD(DCM)/B3LYP-D3/6-31+G(d) level of theory.

System NBu₄BF₄ – computational data

Figure 3.34: [Figure S35]. Ion association of additive **7c** and the single ions.

The Boltzmann-averaged free reaction energy of the ion pairing of **7c** amounts to $\Delta G_{\text{qh},298,\text{corr}} = +11.2 \text{ kJ mol}^{-1}$ in DCM solution. Focusing only on the best conformers of the reactants and product the free reaction energy of the ion pairing of **7c** changes to $\Delta G_{\text{qh},298,\text{corr}} = +9.58 \text{ kJ mol}^{-1}$ in DCM solution. The blue marked cells show the Boltzmann-averaged values.

According to $\Delta G_{\text{qh},298,\text{corr}} = -RT \ln K$ and assuming $R = 8.314 \text{ J K}^{-1} \text{ mol}^{-1}$ and $T = 298.15 \text{ K}$, the respective equilibrium constant amounts to $K(\mathbf{7c}, \text{DCM}) = 0.021$ for the best conformer of **7c** and to $K(\mathbf{7c}, \text{DCM}) = 0.011$ for the Boltzmann-averaged free reaction energy. In this case the equilibrium constant K corresponds to the concentration of the reactants and products in the following way: $K = [\mathbf{7c}]/[\text{BF}_4] [\text{c_NBu4}] = [\mathbf{7c}]/[\text{BF}_4]^2$.

System PBu_4BF_4 – computational data

Figure 3.35: [Figure S36]. Ion association of additive **7d** and the single ions.

The Boltzmann-averaged free reaction energy of the ion pairing of **7d** amounts to $\Delta G_{qh,298,corr} = +5.97 \text{ kJ mol}^{-1}$ in DCM solution. Focusing only on the best conformers of the reactants and product the free reaction energy of the ion pairing of **7d** changes to $\Delta G_{qh,298,corr} = +5.82 \text{ kJ mol}^{-1}$ in DCM solution. The blue marked cells show the Boltzmann-averaged values.

According to $\Delta G_{\text{qh},298,\text{corr}} = -RT \ln K$ and assuming $R = 8.314 \text{ J K}^{-1} \text{ mol}^{-1}$ and $T = 298.15 \text{ K}$, the respective equilibrium constant amounts to $K(\mathbf{7d}, \text{DCM}) = 0.096$ for the best conformer of **7d** and to $K(\mathbf{7d}, \text{DCM}) = 0.090$ for the Boltzmann-averaged free reaction energy. In this case the equilibrium constant K corresponds to the concentration of the reactants and products in the following way: $K = [\mathbf{7d}]/[\text{BF}_4] [\mathbf{d_PBu4}] = [\mathbf{7d}]/[\text{BF}_4]^2$.

3.2 Additional Results

3.2.1 Solvent Effects on Pyridinamide Ion Pairs

Conductivity measurements of pyridinamide ion pairs were carried out in tetrahydrofuran (THF) and chloroform (CHCl_3). The conductivity profiles were analyzed with the simple 1:1 association model (see Chapter 2.1.4) and the resulting association constants K_{IP} (M^{-1}) together with the association constant obtained from conductivity measurements performed in MeCN and DCM are listed in Table 3.64. Further evaluation using other association models were not performed.

Table 3.64. Association constant K_{IP} (M^{-1}) obtained by employing eq. 3.6 of pyridinamide ion pairs in various solvents.

[a] not determined due to solubility problem. [b] reliable conductivity measurement not possible due to pronounced ion association at low concentration.

The association constants of all pyridinamide ion pair increased significantly with decreasing solvent polarity when transitioning from MeCN to DCM to THF to CHCl_3 , indicating the weakest association in the polar protic solvent MeCN and the strongest in the apolar solvent CHCl_3 . Simultaneously, the specific molar conductivities Λ_{m} decreased with decreasing solvent polarity, reflecting the same trend in ion association. The association constants K_{IP} (M^{-1}) were analyzed in relation to several solvent descriptors (see Table 3.65). These included the relative permittivity ϵ_r , which measures the solvent's ability to reduce electrostatic interactions between charges species^[37], and the $E_{\text{T}}(30)$ values, which reflect the solvent polarity based on the solvatochromic shift of the Reichardt's dye^[38–41]. Additionally, the Gutmann acceptor number (AN), representing the solvent's Lewis acidity, and the Gutmann donor number (DN), reflecting the solvent's Lewis basicity, were considered.^[42,43]

Table 3.65. List of solvent descriptors: relative permittivity ϵ_r values^[37], $E_{\text{T}}(30)$ ^[38–41], and Gutmann acceptor (AN) and Gutmann donor (DN) numbers^[42,43] for selected solvents.

	ϵ_r	$E_{\text{T}}(30)$ (kcal mol ⁻¹)	AN	DN
MeCN	36.6	45.6	18.9	14.1
DCM	9.08	40.7	20.4	1.0
THF	7.52	37.4	8.0	20.0
CHCl_3	4.81	39.1	23.1	4.0

Correlating the association constant of each ion pair with the relative permittivity ϵ_r or the Gutmann's AN and DN across all four solvents gave only weak correlations ($R^2 = 0.7 - 0.5$) at best. Stronger correlation ($R^2 > 0.7$) were observed between the association constant and the $E_{\text{T}}(30)$ values, as exemplified for salt **3a** in Figure 3.38A. Due to overly strong associations in CHCl_3 at low concentrations ($c < 0.03$ mM), the earlier made assumption of fully dissociated ions may not hold. Therefore, the association constant obtained in CHCl_3 was excluded from the final analysis, which resulted in a stronger correlation between K_{IP} and the $E_{\text{T}}(30)$ values as exemplary shown for salt **3a** in Figure 3.38B).

Figure 3.38. A) The correlation between the $E_T(30)$ values and K_{IP} for salt **3a** in MeCN, DCM, THF, and CHCl₃, and B) the correlation between the $E_T(30)$ and K_{IP} for salt **3a** in MeCN, DCM, and THF.

Plotting the logarithmic association constants against the solvent descriptors according to the Eyring equation significantly improved the respective correlations. While the correlation of the logarithmic association constants with the Gutmann's AN and DN across all four solvents remained weak ($R^2 < 0.3$), the correlation of the logarithmic association constants with the relative permittivity ϵ_r and the $E_T(30)$ values was strong ($R^2 > 0.9$), as shown exemplary for salt **3a** in Figure 3.39A for the $E_T(30)$ values. Here, excluding the association constant determined in CHCl₃ for salt **3a**, due to potentially overly strong ion association at low concentration, had only a minor effect on the correlation between $\log K_{IP}$ and the $E_T(30)$ values (see Figure 3.39B).

Figure 3.39. A) The correlation between the $E_T(30)$ values and $\log(K_{IP})$ for salt **3a** in MeCN, DCM, THF, and CHCl₃, and B) the correlation between the $E_T(30)$ and $\log(K_{IP})$ for salt **3a** in MeCN, DCM, and THF.

To access the effect of solvent polarity on the reactivity of pyridinamide ion pairs, the reaction rates of electrophile **8a** reacting with salt **3a** were measured across a salt concentration of $[3a] = 0.01 - 4.0$ mM in MeCN, DCM, THF, and CHCl₃ (see Figure 3.40).

In MeCN, a linear correlation is observed between the pseudo-first order rate constant k_{obs} and the salt concentration $[3a]$. In DCM, the initial correlation is linear ($[3a] < 0.04$ mM) until the association equilibrium shifted towards a higher fraction of ion aggregates as the concentration increased. A similar observation is made in THF and CHCl₃, though, the pseudo-first order rate constants k_{obs} are significantly higher than in MeCN and DCM. Furthermore, k_{obs} values measured in THF are higher than in CHCl₃. This is likely caused by a reduced reactivity of the salt due to a stronger association in CHCl₃ than in THF, as already indicated by the association constants K_{IP} (M⁻¹) in Table 3.64. In CHCl₃ the association equilibrium shifts towards higher aggregates at lower concentrations than in THF, thus impacting the reaction rates at lower concentrations. It should be noted that the visible plateaus in THF and CHCl₃ cannot be conclusively ascribed to the diminished reactivity caused by a shift in the association equilibrium since

k_{obs} values higher than 500 s^{-1} are no longer reliable since the boundaries of the stopped-flow machine are reached according to the manufacturer.

Figure 3.40. A) Correlation of k_{obs} for the reaction of **8a** with **3a** for salt concentrations $[\mathbf{3a}] = 0.01 - 4.0 \text{ mM}$ in MeCN and DCM at 20°C . B) Correlation of k_{obs} for the reaction of **8a** with **3a** for salt concentrations $[\mathbf{3a}] = 0.01 - 0.2 \text{ mM}$ in DCM, THF, and CHCl_3 at 20°C .

To check for correlation with solvent descriptor, the second-order rate constant k_2 of salt **3a** were used. The rate constants $k_{2,\text{MeCN}}(\mathbf{3a}) = 7.16 \times 10^3 \text{ M}^{-1} \text{ s}^{-1}$ and $k_{2,\text{DCM}}(\mathbf{3a}) = 1.82 \times 10^6 \text{ M}^{-1} \text{ s}^{-1}$ were obtained using five data points for a concentration window of $[\mathbf{3a}] = 0.01 - 0.03 \text{ mM}$ (see Chapter 2.1.7). Rate constants in THF and CHCl_3 were extrapolated using the first two data points of the wide range measurement, which gave $k_{2,\text{THF}}(\mathbf{3a}) = 3.78 \times 10^7 \text{ M}^{-1} \text{ s}^{-1}$ and $k_{2,\text{CHCl}_3}(\mathbf{3a}) = 3.98 \times 10^7 \text{ M}^{-1} \text{ s}^{-1}$. Correlating the logarithmic values of these second-order rate constants with the solvent descriptors listed in Table 3.65 revealed no correlation with the Gutmann's AN and DN ($R^2 < 0.1$), but a strong correlation ($R^2 > 0.9$) between $\log k_2(\mathbf{3a})$ with the relative permittivity ϵ_r and with the $E_{\text{T}}(30)$ values (see Figure 3.38). This trends, which were also observed for the logarithmic association constants $\log K_{\text{IP}}$, suggests that the solvent polarity plays a significant role in the association behavior and reactivity of pyridinamide ion pairs.

Figure 3.41. Correlation between the $E_{\text{T}}(30)$ values and logarithmic second-order rate constants $\log k_2 (\text{M}^{-1} \text{ s}^{-1})$ for salt **3a** in MeCN, DCM, THF, and CHCl_3 .

Finally, it should be noted that no further kinetic measurements in THF and MeCN have been performed due to the high reaction speed of **8a** reacting with **3a**. The benzhydrylium salt **8a**, with an electrophilicity parameter $E = -10.04$ is the least reactive benzhydrylium salt. Therefore, any other benzhydrylium salt would react even faster when used as electrophile in this measurement.

3.2.2 Association Model Validity at Higher Concentrations.

The conductivity profiles of pyridinamide ion pairs in dichloromethane (DCM) have been studied at salt concentrations up to 1.0 mM , with a thorough analysis of three possible ion association models (see

Chapter 2.1.4 and 3.1.4). Although this concentration range has been extensively studied and optimized, typical synthetic applications often involve catalyst concentrations of 1.0 mM or higher. To assess the robustness of the established association models beyond 1.0 mM, conductivity measurements were extended to 5.0 mM, and the root mean square error (RMSE) between experimental data and simulations using previously optimized association constants was calculated. The RMSE values, summarized in Table 3.2 and Table 3.3, show that at 1.0 mM, the RMSE is below 1.0 mM across all models, indicating a good fit between experimental and simulated data. However, when extending the concentration to 5.0 mM, the RMSE increases (see Table 3.66).

Table 3.66. List of specific molar conductivities Λ_m ($\text{S cm}^2 \text{ mol}^{-1}$) and the resulting ion association constant K_{IP} (M^{-2} , Model 1), the cationic and anionic sandwich association constants K_{CAC} and K_{ACA} (M^{-2} , Model 2), and the scaling factors α and β to obtain the association constants of the mixed association (model 3) with the respective RMSE values for salt concentration up to 5.0 mM for all pyridinamide ion pairs in DCM.

Ion Pair	Λ_m ($\text{S cm}^2 \text{ mol}^{-1}$)	Model 1 K_{IP} (M^{-2}) (RMSE)	Model 2a K_{CAC} (M^{-2}) (RMSE)	Model 2b K_{ACA} (M^{-2}) (RMSE)	Model 3 [α β] $\times K_{CAC}$ (M^{-2}) (RMSE)
3d	56.0	7.35×10^6 (2.55)	1.07×10^7 (3.32)	—	—
3c	57.9	5.00×10^6 (3.44)	1.01×10^7 (4.25)	1.01×10^7 (4.25)	[33 23] $\times 1.01 \times 10^7$ (6.17)
3b	80.3	2.96×10^5 (11.4)	4.65×10^6 (4.85)	4.65×10^6 (4.85)	[100 0] $\times 4.65 \times 10^6$ (4.85)
3a	79.2	6.86×10^5 (11.4)	6.38×10^6 (6.71)	6.38×10^6 (6.71)	[44 21] $\times 6.38 \times 10^6$ (2.29)
4a	73.6	8.79×10^5 (10.5)	6.50×10^6 (5.16)	6.50×10^6 (5.16)	[12 61] $\times 6.50 \times 10^6$ (2.23)
5a	73.2	6.92×10^5 (9.31)	5.15×10^6 (5.71)	5.15×10^6 (5.71)	[11 67] $\times 5.15 \times 10^6$ (1.12)
6a	74.2	6.89×10^5 (7.16)	6.75×10^6 (4.41)	6.75×10^6 (4.41)	[16 52] $\times 6.75 \times 10^6$ (1.12)

A progressive decrease in RMSE is observed as the model evolves from the 1:1 ion association to the sandwich association and finally to the mixed sandwich association model. This is graphically depicted in Figure 3.42 for salt **3a** as example. In the 1:1 association model beyond 1.0 mM the simulated conductivity profile is clearly below the experimental data point, yielding a RMSE of 11.4. Opposed to this, in the sandwich association model (Model 2) the simulated curve runs above the experimental data, however, the deviation is smaller, yielding an RMSE of 6.71. In the final association model, the mixed sandwich association model, the experimental data points, and the simulated curve are almost overlapping as indicated by the significantly reduced RMSE of 2.29.

Figure 3.42. Conductivity profile for salt **3a** in DCM with fits to the calculated conductivity data for the 1:1 association model (purple dotted-dashed line), the cationic and anionic sandwich association models (grey line and blue long dashed line), and mixed sandwich association model (brown short-dashed line) with their respective percentual residue.

The RMSE for the final mixed sandwich model at 5.0 mM is notably lower compared to the initial 1:1 ion association model, indicating substantial improvements in the accuracy of the association model with increasing complexity. This demonstrates that the mixed sandwich association model is more accurate

for predicting the behavior of pyridinamide ion pairs at higher concentrations, relevant to practical synthetic conditions. This trend is observed for all pyridinamide ion pairs, except salt **3c** and **3d**.

While the RMSE at 1.0 mM decreases during the model refinement (see Table 3.2 and Table 3.3), a different trend is observed when extending to 5.0 mM. Here, the RMSE progressively increases as the model transitions from the 1:1 ion association to the sandwich association and finally to the mixed sandwich association model. As salt **3c** and **3d** contain *n*-butyl chained cations, their association behavior at higher concentration might differ from other ion pairs carrying cations with aromatic substituents (cation **a** and **b**). The association constants of salt **3c** and **3d** suggest a stronger ion association, which could potentially lead to 1:1 ion pairs or other symmetric higher-order aggregates rather than following an asymmetric sandwich association at higher concentrations as observed with other pyridinamide salts.

Looking forward, future synthesis efforts for pyridinamide ion pair will focus on selecting ion combination that preferentially favor the cationic sandwich association, thereby ensuring a high concentration of free anions, which are responsible for the enhanced reactivity observed for these systems in apolar solvents.

3.2.3 Additional Experimental Data

Chapter 4. Application of Ion Pair Catalysts in Acylation Reactions

4.1 Introduction

Lewis base catalyzed acylation reactions are among the most relevant organocatalytic transformations due to their extensive use in protection chemistry and in enantioselective applications^[1] and they have been widely studied utilizing Lewis base catalysts such as DMAP (**1**) and its analogs.^[2–5] The currently accepted mechanism of acylation of alcohols catalyzed by DMAP-based Lewis bases is shown in Scheme 4.1 and starts with the preequilibrium between DMAP and the acyl donor forming an acyl pyridinium cation **12**. This intermediate subsequently reacts with the alcohol in the rate-determining step via transition state **13** to form the ester product **14** and the deactivated (protonated) catalyst. The regeneration of the active catalyst usually requires an auxiliary base such as triethylamine (NEt₃).^[2,6]

Scheme 4.1. Reaction mechanism of acylation reaction with DMAP (**1**).

When using an anionic catalyst, the catalytic pathway is expected to be almost identical with the main difference being the charge distribution of the substrate-catalyst adduct **15** as shown in Scheme 4.1. The catalytic efficiency of DMAP-type catalysts in acyl-transfer reactions is influenced by two main factors. The first one being the formation and stabilization of the acylpyridinium **12**. The second is the type of acyl donor, since the counterion X[−] of the acylpyridinium cation **12** formed in the preequilibrium critically affects the transition state **13**. It was found, that acylation reactions of tertiary alcohols employing anhydrides proceed faster than with acetyl chloride.^[7] The importance of the counterion X[−] on the reaction rate was noted by several researchers.^[8–10] It was suggested that the acetyl anion promotes the deprotonation of the hydroxyl group in transition state **13** best in comparison to otherwise generated acids using other acyl donors. Therefore, anhydrides are most often used for acylation reactions.^[6,11]

In the past, the acylation reaction of 1-ethynylcyclohexanol (**16**) with acetic anhydride (**17**) yielding ester **18**, as it is shown in Scheme 4.2, has been used as a benchmark reaction for newly developed Lewis base catalyst.^[3,4] Therefore, it was also used to test the catalytic potential of pyridinamide salts and to investigate their behavior in reactions that produce an acidic byproduct in the catalytic cycle.

4.2 Results and Discussion

4.2.1 Steglich Acylation

The catalytic efficiency of pyridinamide ion pairs was investigated using the in Scheme 4.2 depicted *Steglich*^[12] acylation reaction as a secondary benchmark reaction following the synthesis of urethane **11** as the primary benchmark reaction (see Chapter 3). In this reaction, 1-ethynylcyclohexanol (**16**, 0.2 M) was reacted with acetic anhydride (**17**, 0.4 M) and NEt₃ (0.6 M) as an auxiliary base in deuterated Chloroform (CDCl₃). The progress was monitored by ¹H-NMR using the protons marked in bold in Scheme 4.2. The objective was to assess the performance of pyridinamide ion pairs in reactions that generate an acid as a side product, as it commonly observed in acylation reactions involving anhydrides.

Scheme 4.2. Acylation reaction of 1-ethynylcyclohexanol (**16**) with acetic anhydride (**17**) in CDCl₃.

The catalytic performance of organocatalysts **1** and **2** was compared with that of pyridinamide ion pair catalysts **3a-d** and **4-6a**. The corresponding effective reaction rates k_{eff} (M⁻¹ s⁻¹) are listed in Table 4.1, showing the reaction rates for each catalyst alongside their respective half-life times $t_{1/2}$ (sec). The results demonstrate a range of catalytic activity across different classes of catalysts.

Table 4.1. Effective reaction rates k_{eff} (M⁻¹ s⁻¹) and half-life times $t_{1/2}$ (sec) for the acylation benchmark reaction using DMAP (**1**), TCAP (**2**) and pyridinamide salts **3a-d** and **4-6a** in CDCl₃.

catalyst	k_{eff} (M ⁻¹ s ⁻¹) ^[a]	$t_{1/2}$ (s) ^[a,b]	$t_{1/2}$ (min) ^[a,b]
2	7.03×10^{-2}	1792	29.9
6a	3.70×10^{-2}	3011	50.2
5a	1.38×10^{-2}	6968	116
3b	1.33×10^{-2}	6698	112
4a	1.30×10^{-2}	7416	124
3a	1.15×10^{-2}	7494	125
3c	4.85×10^{-3}	17200	287
1	4.50×10^{-3}	17750	296
3d	4.05×10^{-3}	20750	346

[a] average values of two measurement. [b] extracted from simulation data generated with COPASI.

Based on the turnover curves of the Steglich acylation reaction, the ion pair catalysts were classified into three distinct groups. Group A consisted of ion pairs **3c** and **3d**, which contain unbranched alkyl cations. Their catalytic activity was comparable to DMAP (**1**) in this acylation. Group B included ion pairs **3a**, **3b**,

4a, and **5a**, all of which contain aromatic cations. The ion pairs in Group B demonstrated approximately three times higher catalytic activity than those in Group A. Interestingly, despite the higher Lewis and Brønsted basicity and nucleophilicity of ion pairs **4a** and **5a**, their effective reaction rates were comparable to those of ion pair **3a** and **3b**. Group C, represented solely by ion pair **6a**, displayed the highest catalytic efficiency among the ion pair catalysts, although the neutral organocatalyst TCAP (**2**) remained the most efficient catalyst in this series, outperforming ion pair **6a** by a factor of two.

To further explore the relationship between catalytic efficiency and molecular properties, the logarithmic effective reaction rates $\log(k_{\text{eff}})$ of the pyridinamide salts were correlated in Figure 4.1 with the logarithmic bimolecular rate constant $\log(k_{2,8a})$, methyl cation affinities (ΔMCA), and $\text{p}K_{a2}$ values, all introduced in Chapter 3. This correlation analysis provided insights into how nucleophilicity and basicity contribute to the overall catalytic performance of pyridinamide ion pairs.

Figure 4.1. Correlation of A) $\log(k_{\text{eff}})$ vs. bimolecular rate constant $\log k_{2,8a}$ for pyridinamide ion pair catalysts. B) $\log(k_{\text{eff}})$ vs. $\text{p}K_{a2}$ values in $\text{H}_2\text{O}/\text{MeCN} = 1:1$. C) $\log(k_{\text{eff}})$ vs. Lewis basicity parameter ΔMCA (calculations are listed in Chapter 3.1.10.2).

The effective reaction rates k_{eff} of pyridinamide salts in the urethane benchmark reaction showed a strong linear correlation with each reactivity parameter ($R^2 > 0.9$, see Chapter 3), indicating a clear relationship between nucleophilicity, Brønsted basicity, Lewis basicity, and catalytic efficiency. However, in the Steglich acylation reaction, no such correlation was observed when all seven pyridinamide ion pairs were analyzed (see Figure 4.1_A1/B1/C1). When salts **4a** and **5a** were excluded from the analysis, the effective reaction rates k_{eff} of the remaining five pyridinamide catalysts correlated linearly with the logarithmic bimolecular rate constants k_2 for their reaction with benzhydryl cation **8a** (see Figure 4.1_A2).

Similarly, a linear correlation was observed with their relative Lewis basicity parameter ΔMCA (see Figure 4.1_C2).

Thus, the high nucleophilicity and basicity of salts **4a** and **5a** do not translate into the expected high catalytic reactivity. Comparable observations have been made for 3,4,5-triaminopyridines of type **D** (see Chapter 1, Chart 1.1) which also displayed a lower catalytic activity than their high Lewis basicity and high nucleophilicity values would have suggested.^[4] One possible explanation for the comparably low catalytic activity of salts **4a** and **5a** could be an increased stabilization of the acylpyridinium **12** formed in the first reaction step. This might raise the energy barrier of the subsequent alcohol acylation *via* intermediate **13** (see Scheme 4.1).^[13,14] To test this hypothesis, quantum chemical calculations comparing the Gibbs free reaction energies of anhydride **17** reacting with catalyst **1**, **3a**, and **5a** are recommended. Additionally, spectroscopic analysis of the mixtures of anhydride **17** with these catalysts could be conducted to detect the acylated intermediate **12**. This approach has been proven effective in previous studies.^[14]

4.2.2 Influence of the Auxiliary Base

The reduced catalytic efficiency of salts **4a** and **5a** could also be attributed to partial deactivation of the catalyst via protonation. This deactivation might occur at the end of the catalytic cycle, where NEt_3 might be unable to fully regenerate the pyridinamide anion, thus leaving the catalyst inactive. Another possible source of protonation could be the acetic acid formed as a byproduct during the consumption of acetic anhydride, which would further neutralize the basic catalyst. To investigate this hypothesis, the benchmark reaction was repeated using ion pair catalyst **5a** in combination with various bases. Ion pair **6a**, which demonstrated the highest catalytic activity in this benchmark reaction, was used as the reference salt. The corresponding effective reaction rates k_{eff} ($\text{M}^{-1} \text{s}^{-1}$) are presented in Table 4.2.

Table 4.2. Effective reaction rate k_{eff} ($\text{M}^{-1} \text{s}^{-1}$) for salt **5a** and **6a** with various auxiliary bases in CDCl_3 .

cat	k_{eff} ($\text{M}^{-1} \text{s}^{-1}$)			
	NEt_3	NPr_3	DIPEA	HMPN
5a	1.38×10^{-2}	1.30×10^{-2}	$1.32 \times 10^{-2[a]}$	$1.27 \times 10^{-3[a]}$
6a	3.70×10^{-2}	3.37×10^{-2}	–	–

[a] k_{eff} obtained in a single measurement.

Replacing NEt_3 with tri-propylamine (NPr_3) did not result in an increase in catalytic activity either for salt **5a** or **6a**. Instead, a slight decrease in reaction rate for salt **6a** was noted. Similarly, the use of the stronger, sterically hindered base diisopropylethylamine (DIPEA, Hünig base) or 1,8-bis(hexamethyltriaminophosphazenylnaphthalene (HMPN) failed to enhance the benchmark reaction catalyzed by salt **5a**. It is notable that the significant steric hindrance presented by the proton sponge resulted in a 10-fold reduction in the effective reaction rate k_{eff} (**5a**) (see Table 4.2). These findings are in agreement with previous studies where more sterically hindered auxiliary bases would slow down the reaction.^[15] Based on these results, it can be concluded that the reduced catalytic activity of salt **4a** and **5a** was unlikely caused by deactivation through protonation.

4.2.3 Solvent Effects

Before starting the investigation of the Steglich acylation with various catalysts, the benchmark reaction was performed in three selected organic solvents. Previous research has shown that Lewis-base catalyzed acylation reactions perform optimally in apolar organic solvents, while reaction rates tend to decrease in polar solvents.^[4,16,17] In both conductometric measurements and nucleophilicity measurements, the choice of solvent was found to significantly affect the behavior of the ion pairs (see Chapter 2 and 3). Thus, catalyst **5a**, one of the most active pyridinamide catalysts in previous benchmark reactions, was

selected to further evaluate solvent effects on ion pair catalysts in this benchmark reaction. For comparison, these kinetic studies were conducted using DMAP (**1**) as a neutral organocatalyst.

The influence of solvents on the benchmark reaction was evident for both investigated catalysts. For DMAP, a stepwise increase in the reaction rates was noted with increasing solvent polarity ($\text{MeCN-d}_3 < \text{DCM-d}_2 < \text{CDCl}_3$). Simultaneously, the effect was more pronounced for **5a**. Upon replacing MeCN-d_3 with DCM-d_2 , the rate constant increased by a factor of 1.7, whereas the difference between the rate constants in CDCl_3 and DCM-d_2 was approximately half of this value.

Table 4.3. List of effective reaction rate k_{eff} ($\text{M}^{-1} \text{s}^{-1}$) and half-life times (min) for DMAP (**1**) and salt **5a** in the Steglich benchmark acylation in CDCl_3 , DCM-d_2 , and MeCN-d_3 .

Catalyst	Solvent	k_{eff} ($\text{M}^{-1} \text{s}^{-1}$)	$t_{1/2}$ (sec)	$t_{1/2}$ (min)
1	CDCl_3	4.50×10^{-3}	17750	296
	DCM-d_2	$2.58 \times 10^{-3[a]}$	31800 ^[a]	530 ^[a]
	MeCN-d_3	$1.53 \times 10^{-3[a]}$	54400 ^[a]	907 ^[a]
5a	CDCl_3	1.38×10^{-2}	6968	116
	DCM-d_2	$7.81 \times 10^{-3[a]}$	12000 ^[a]	200 ^[a]
	MeCN-d_3	7.39×10^{-4}	11550	1925

[a] k_{eff} obtained in a single measurement.

The effective reaction rates k_{eff} were analyzed in relation to several solvent descriptors listed in Table 4.4. These included the relative permittivity ϵ_r , which measures the solvent's ability to reduce electrostatic interactions between charged species, and the $E_T(30)$ values, which reflect the solvent polarity based on the solvatochromic shift of the Reichardt's dye. Additionally, the Gutmann acceptor number (AN), representing the solvent's Lewis acidity, and the Gutmann donor number (DN), reflecting the solvent's Lewis basicity, were considered.

Table 4.4. List of solvent descriptors: relative permittivity ϵ_r values^[18], $E_T(30)$ ^[19–22], and Gutmann acceptor (AN) and Gutmann donor (DN) numbers^[23,24] for selected solvents CDCl_3 , DCM-d_2 and MeCN-d_2 .

	ϵ_r	$E_T(30)$ (kcal mol^{-1})	AN	DN
CDCl_3	4.81	39.1	23.1	4.0
DCM-d_2	9.08	40.7	20.4	1.0
MeCN-d_3	36.6	45.6	18.9	14.1

Correlating the logarithmic effective reaction rate $\log k_{\text{eff}}$ with the respective solvent descriptors using the Eyring equation gave the following results: all correlation were solid to strong, with the exception of the weak correlation of $\log k_{\text{eff}}(\mathbf{1})$ with the Gutmann donor numbers (DN) which had an R^2 of 0.5 (see Table 4.5). For pyridinamide ion pair **5a**, the strongest correlation were observed between $\log k_{\text{eff}}$ with the relative permittivity ϵ_r as well as the $E_T(30)$ values ($R^2 < 0.9$).

These findings suggested that the most decisive solvent properties are its ability to permit electrostatic interactions between charged species, and its polarity. Subsequent kinetic measurements of the remaining ion pair catalysts were carried out in CDCl_3 , where the highest catalytic activity for both catalysts was observed.

Table 4.5. Correlations between the logarithmic effective reaction rate $\log(k_{\text{eff}})$ ($\text{M}^{-1} \text{s}^{-1}$) with the respective solvent descriptors relative permittivity ϵ_r ^[18], $E_T(30)$ (kcal mol^{-1})^[19–22], and Gutmann acceptor (AN) and Gutmann donor (DN) numbers^[23,24] for catalysts **1** and **5a**.

	5a		1	
	Equation	R^2	Equation	R^2
$E_T(30)$ (kcal mol^{-1})	$\log k_{\text{eff}}(\mathbf{5a}) = -0.20 \times E_T(30) + 5.95$	0.997	$\log k_{\text{eff}}(\mathbf{1}) = -0.07 \times E_T(30) + 0.18$	0.911
ϵ_r	$\log k_{\text{eff}}(\mathbf{5a}) = -0.04 \times \epsilon_r - 1.71$	0.996	$\log k_{\text{eff}}(\mathbf{1}) = -0.01 \times \epsilon_r - 2.38$	0.846
AN	$\log k_{\text{eff}}(\mathbf{5a}) = 0.28 \times \text{AN} - 8.14$	0.769	$\log k_{\text{eff}}(\mathbf{1}) = 0.11 \times \text{AN} - 4.85$	0.979
DN	$\log k_{\text{eff}}(\mathbf{5a}) = -0.09 \times \text{DN} - 1.79$	0.844	$\log k_{\text{eff}}(\mathbf{1}) = -0.03 \times \text{DN} - 2.43$	0.523

4.2.4 Acylation with Benzoic Anhydride

The response of pyridinamide ion pair catalysts to changes in the steric demand of the acylation reagent was tested by reacting tertiary alcohol **16** with benzoic anhydride **19** to obtain ester **20**, as shown in Scheme 4.3. These studies were performed under the same reaction conditions as the Steglich acylation benchmark reaction, utilizing the four selected ion pair catalysts **3a**, **3d**, **4a**, and **6a**, along with TCAP (**2**) as neutral reference organocatalyst. Due to the prolonged reaction time (approx. 4 weeks) required for ion pair catalyst **3a** and **3d**, kinetic measurements were only conducted once. The reaction was monitored over a 30-day period without achieving full conversion for **3a** and **3d**. In contrast, the reaction times of the other selected catalysts, **2**, **4a**, and **6a**, were significantly shorter, taking approx. 14 days or less.

**Scheme 4.3.** Acylation reaction of 1-ethynylcyclohexanol (**16**) with benzoic anhydride (**19**).

The observed effective reaction rates k_{eff} for acylation using benzoic anhydride **19** were generally slower compared to acylation using acetic anhydride **17** across the examined catalysts (see Table 4.6). The ratio of the k_{eff} values for both benchmark reactions indicated how sensitive each catalyst responded to the increase in steric demand. The ratio showed a similar trend in the lower catalytic activity for catalysts **2**, **3a**, **3d**, and **6a**. In contrast, catalyst **4a** exhibited the least sensitivity to the increased steric demand of the acylating agent, resulting in a smaller disparity in catalytic performance between catalysts **6a** and **4a**. Specifically, the difference in activity decreased from an approx. threefold difference in the acylation with acetic anhydride **17** to a factor of 1.3 in the acylation with benzoic anhydride **19**.

Table 4.6. Comparison of effective reaction rates k_{eff} ($\text{M}^{-1} \text{s}^{-1}$) for acylation with acetic anhydride **17** ($k_{\text{eff,AA}}$) and benzoic anhydride **19** ($k_{\text{eff,BA}}$) and the ratio of those two parameters.

[a] $k_{\text{eff,BA}}$ obtained in a single measurement.

A comparable effect was noted between catalysts **6a** and **2**, though the magnitude of change was significantly smaller and catalyst **2** remained the most active in this series. Quantum chemical calculations are recommended to assess the stability of the respective acylpyridinium intermediate **12** generated in the acylation reaction with benzoic anhydride. Future studies in this direction might reveal the reason for the lower sensitivity of catalyst **4a** towards the increased steric demand of the acylating reagent. Meanwhile, these observations suggest that, with careful selection of reagents and optimization of reaction conditions, ion pair catalysts might have the potential to match the catalytic efficiency of **2** in acylation reactions.

4.2.5 Comparison with Neutral Lewis Base Catalysts

The Steglich acylation reaction (see Scheme 4.2) has been extensively studied by the Zipse group, which has investigated a library of pyridine-based Lewis base catalysts. Over the years, different concepts were explored to enhance the catalytic activity. The most promising Lewis base catalysts, with a catalytic activity comparable to or better than TCAP (**2**), are listed in Table 4.7.

Table 4.7. Half-life time $t_{1/2}$ (min) of Lewis base catalysts measured for acylation reaction of alcohol **16** with anhydride **17**.

Catalyst	$t_{1/2}$ (min) for 10 mol% of cat.	$t_{1/2}$ (min) for 5.0 mol% of cat.
2	14.7 ± 0.1 ^[3]	29.9 ^[a]
6a	—	50.2 ^[a]
21	18.0 ± 0.1 ^[3]	36.0 ^[b]
22	13.8 ± 0.4 ^[4]	27.6 ^[b]
23	38.0 ± 1.5 ^[4]	76.0 ^[b]
24	12.0 ^[25]	24.0 ^[b]
25	5.7 ± 0.1 ^[5]	11.4 ^[b]

[a] this work. [b] estimated assuming a linear correlation between $t_{1/2}$ and catalyst load.

In previous studies, the benchmark reaction of alcohol **16** with anhydride **17** was conducted using 10 mol% of catalyst. To compare the half-life times $t_{1/2}$ (min) of the neutral Lewis base catalysts with the most catalytically active pyridinamide salt **6a**, the half-life time $t_{1/2}$ of the benchmark acylation with 5.0

The evaluation of the catalytic activity of pyridinamide ion pairs using the Steglich acylation reaction revealed three distinguishable groups, based on their catalytic performance. Pyridinamide salts **3c** and **3d** displayed a catalytic efficiency comparable to DMAP (**1**), whereas salts **3a**, **3b**, **4a**, and **5a** showed a threefold increase in activity. The most efficient pyridinamide ion pair catalyst was found to be **6a**, although TCAP (**2**) remained the best performing organocatalyst in this study, with a reaction rate twice as fast as that of salt **6a**.

Despite their high nucleophilicity and basicity, pyridinamide salts **4a** and **5a** displayed only moderate catalytic activity. This lack in catalytic activity led to investigations of potential deactivation *via* protonation, which was ruled out by testing various auxiliary bases in the benchmark reaction. However, quantum chemical calculations comparing the Gibbs free reaction energies of anhydride **17** reacting with catalyst **1**, **3a**, and **5a** are recommended as an increased stabilization of the acylated pyridinium intermediate **12** might negatively affect the energy barrier of the following reaction steps. The choice of solvent as well as the steric demand of the anhydride had a considerable impact on the reaction rates, emphasizing the importance of these variables in acylation reactions.

While pyridinamide salts were effective in acylation reaction, several other Lewis base catalysts proved to be more efficient. Nevertheless, the majority of these organocatalysts are either expensive or require a complex synthetic procedure. Pyridinamide ion pairs, which can be synthesized in a straightforward, rapid, and cost-effective manner, offer a viable alternative. To fully exploit their catalytic potential, it is recommended to employ pyridinamide salts primarily in addition reactions or rearrangement reactions, where acidic byproducts would not interfere with their catalytic effectiveness.

In summary, this study provided valuable insights into the performance of pyridinamide ion pairs in acylation reactions. The possibility to synthesize these catalysts easily and at low cost, combined with their moderate efficiency, presents a promising avenue for further exploration, particularly in reactions where acidic byproducts are not an issue.

mol% catalyst was estimated for catalysts **21**, **22**, **23**, **24**, and **25**, assuming a linear correlation between $t_{1/2}$ and the catalyst load. This linear correlation has been previously established for several catalysts in different benchmark reaction, including pyridinamide ion pair catalysts^[4,26]. Comparing the measured and estimated half-life times $t_{1/2}$ of the Lewis bases catalysts listed in Table 4.7 showed that catalyst **25** is the most catalytically active catalyst, followed by TMAJ (**24**). 3,4-Diaminopyridine derivatives **21** and **22** exhibit catalytic activities directly comparable to TCAP (**2**), with **22** reacting slightly faster. As already mentioned, pyridinamide salt **6a** reacted slower than TCAP by a factor of two. However, the lowest catalytic activity was exhibited by 3,4,5-triaminopyridine derivative **24**.

4.3 Conclusion

The evaluation of the catalytic activity of pyridinamide ion pairs using the Steglich acylation reaction revealed three distinguishable groups, based on their catalytic performance. Pyridinamide salts **3c** and **3d** displayed a catalytic efficiency comparable to DMAP (**1**), whereas salts **3a**, **3b**, **4a**, and **5a** showed a threefold increase in activity. The most efficient pyridinamide ion pair catalyst was found to be **6a**, although TCAP (**2**) remained the best performing organocatalyst in this study, with a reaction rate twice as fast as that of salt **6a**.

Despite their high nucleophilicity and basicity, pyridinamide salts **4a** and **5a** displayed only moderate catalytic activity. This lack of catalytic activity led to investigations of potential deactivation *via* protonation, which was ruled out by testing various auxiliary bases in the benchmark reaction. However, quantum chemical calculations comparing the Gibbs free reaction energies of anhydride **17** reacting with

catalysts **1**, **3a**, and **5a** are recommended, as an increased stabilization of the acylated pyridinium intermediate **12** might raise the energy barrier of the following reaction steps. The choice of solvent, as well as the steric demand of the anhydride, had a considerable impact on the reaction rates, emphasizing the importance of these variables in acylation reactions.

While pyridinamide salts are effective in acylation reactions, several other Lewis base catalysts proved to be more efficient. Nevertheless, most of these organocatalysts are either expensive or require a complex synthetic procedure. Pyridinamide ion pairs, which can be synthesized in a straightforward, rapid, and cost-effective manner, offer a viable alternative. To fully exploit their catalytic potential, it is recommended to employ pyridinamide salts primarily in addition reactions or rearrangement reactions, where acidic byproducts would not interfere with their catalytic effectiveness.

In summary, this study provides valuable insights into the performance of pyridinamide ion pairs in acylation reactions. The possibility to synthesize these catalysts easily and at low cost, combined with their moderate efficiency, offers promising opportunities for further applications, particularly in reactions where acidic byproducts are not an issue.

4.4 Experimental Part

4.4.1 General Information

All reagents were purchased from Sigma Aldrich, TCI, or Acros and used without further purification unless otherwise noted. Solvents were obtained from Acros Organics, Sigma Aldrich, or Merck and purified by simple distillation in a rotary evaporator, unless otherwise specified.

All air- and moisture-sensitive reactions were performed under a nitrogen atmosphere and the glassware and magnetic stirrers were dried in a dry oven at 110 °C overnight. CDCl_3 and NEt_3 were dried over CaH_2 and distilled prior to use. MeCN-d_3 , CD_2Cl_2 and CDCl_3 were dried over 4 Å molecular sieves.

Nuclear magnetic resonance (NMR) spectra were recorded on Bruker 400 MHz or INOVA 400 and 600 MHz machines. The following abbreviations were used in the analysis of NMR spectra: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, br s = broad singlet. NMR signals were assigned based on 2D spectra (COSY, HSQC, HMBC) analysis. Chemical shifts were given in ppm. The internal reference was set to the residual solvent signals (CD_2Cl_2 , CDCl_3 , DMSO-d_6 , MeCN-d_3). ^{19}F NMR spectra were referenced using the solvent signal.^[27] The spectra were processed using MestreNova (version 14.1.1).

4.4.2 Experimental Design

As a benchmark reaction the acylation of 1-ethynylcyclohexanol (**16**, 1.0 eq) with acetic anhydride (**17**, 2.0 eq) was chosen. 1,3,5-Trimethoxybenzene was used as internal standard and NEt_3 as the auxiliary base. The reaction progress was traced via ^1H NMR.

Scheme 4.4. Acylation of 1-ethynylcyclohexanol (**16**) with acetic anhydride (**17**) and NEt_3 in deuterated chloroform.

Three stock solutions were prepared in oven-dried 1.0 mL volumetric flasks under N_2 atmosphere. Stock solution A contained 0.6 M 1-ethynylcyclohexanol **16** with 1.8 M NEt_3 . Stock solution B contained 1.2 M acetic anhydride **17** with 0.09 M standard, and stock solution C contained 0.03 M catalyst. Hamilton syringes were used to transfer 0.2 mL of each stock solution in a N_2 flushed NMR tube. ^1H NMR measurements were then taken of the sample in defined time intervals and the bold-marked protons were traced (see Scheme 4.4 and Figure 4.2).

Figure 4.2. NMR spectra of Steglich benchmark reaction with assigned ^1H shift of all compounds.

Eq. 4.1 was used to calculate the conversion of the acylation product at time t , with I being the absolute NMR integral of the ester or the internal standard (Std), N being number of protons of the selected integral, M being the molar mass of the respective compound, m being the weighted mass of the internal standard and the ester at 100 % conversion, and c_0 representing the starting concentration of the alcohol.

$$c_t[\text{ester}] = \frac{I_{\text{ester}}}{I_{\text{Std}}} \times \frac{N_{\text{Std}}}{N_{\text{ester}}} \times \frac{M_{\text{ester}}}{M_{\text{Std}}} \times \frac{m_{\text{Std}}}{m_{\text{ester},100\%}} \times c_0[\text{alcohol}] \quad (4.1)$$

In previous studies, the kinetic half-life time $t_{1/2}$ of the reaction was calculated with eq. 4.2.^[3,4]

$$t_{1/2} = \frac{\ln 1.5}{k_{\text{eff}}[\text{alcohol}]_0} \quad (4.2)$$

In this work the half-life times are extracted in seconds (s) from the kinetic simulations performed in COPASI and converted into minutes (min) for better comparability.

4.4.3 Simulation of Kinetic Experiments – Steglich Acylation with Acetic Anhydride

The secondary rate constants k_{eff} of the acylation reaction were simulated using the program COPASI^[28]. Figure 4.3 shows the simplified mechanism used for the simulation and the equations used for numerical simulation with COPASI.

Figure 4.3. Proposed mechanism of acylation reaction and the employed numerical simulation equation in COPASI to obtain effective rate constant k_{eff} .

Therefore, the time t (sec) and $c_t[\text{ester}]$ were imported into COPASI as a .txt file. With the function “Parameter Estimation” (default settings) the rate constant k_{eff} ($= k_2$) were simulated. The catalyst loading was set to be on the product side with $k_1 = 0.1 \text{ M}^{-1} \text{ s}^{-1}$ and $k_{-1} = 0.001 \text{ M}^{-1} \text{ s}^{-1}$. The catalyst restoration was set to be $k_3 = 0.1 \text{ M}^{-1} \text{ s}^{-1}$. For reaction that did not run to completion the fourth equation “side” reaction” was added and the rate constant k_4 was simultaneously simulated with k_{eff} . The results of the simulations are summarized in Table 4.8.

Table 4.8. Effective reaction rates k_{eff} ($\text{M}^{-1} \text{ s}^{-1}$) and half-life times $t_{1/2}$ (min) for the acylation of 1-ethynylcyclohexanol **16** with acetic anhydride **17** in CDCl_3 .

4.4.4 Simulation of Kinetic Experiments – Acylation with Different Auxiliary Bases

Kinetic measurements performed with different auxiliary bases were prepared and analyzed according to the procedure described in Chapter 4.3.2 and Chapter 4.3.3. The resulting effective reaction rates k_{eff} and half-life times $t_{1/2}$ (min) are summarized in Table 4.18.

Table 4.18. Effective reaction rates k_{eff} ($\text{M}^{-1} \text{s}^{-1}$) and half-life times $t_{1/2}$ (min) for the acylation of 1-ethynylcyclohexanol **16** with acetic anhydride **17** and various auxiliary bases in CDCl_3 .

Catalyst	Base	$k_{\text{eff}} (\text{M}^{-1} \text{s}^{-1})$	Average $k_{\text{eff}} (\text{M}^{-1} \text{s}^{-1})$	$t_{1/2} (\text{s})$	$t_{1/2} (\text{min})$	Average $t_{1/2} (\text{min})$
5a	NEt ₃	1.62×10^{-2}	$1.38 \times 10^{-2} \pm 2.37 \times 10^{-3}$	5975	100	116 ± 16.6
		1.15×10^{-2}		7961	133	
	NPr ₃	1.21×10^{-2}	$1.30 \times 10^{-2} \pm 9.22 \times 10^{-4}$	7632	127	119 ± 8.12
		1.39×10^{-2}		6658	111

4.4.5 Simulation of Kinetic Experiments – Acylation in Different Solvents

Kinetic measurements performed in different deuterated solvents were prepared and analyzed according to the procedure described in Chapter 4.3.2 and Chapter 4.3.3. The resulting effective reaction rates k_{eff} and half-life times $t_{1/2}$ (min) are summarized in Table 4.23.

Table 4.23. Effective reaction rates k_{eff} ($\text{M}^{-1} \text{s}^{-1}$) and half-life times $t_{1/2}$ (min) for the acylation of 1-ethynylcyclohexanol **16** with acetic anhydride **17** in CDCl_3 , DCM-d_2 or MeCN-d_3 .

Catalyst	Base	k_{eff} ($\text{M}^{-1} \text{s}^{-1}$)	Average k_{eff} ($\text{M}^{-1} \text{s}^{-1}$)	$t_{1/2}$ (s)	$t_{1/2}$ (min)	Average $t_{1/2}$ (min)
1	CDCl_3	4.30×10^{-3}	$4.50 \times 10^{-3} \pm 2.00 \times 10^{-4}$	18300	305	296 ± 9.17
		4.70×10^{-3}		17200	287	
	DCM-d_2	2.58×10^{-3}	–	31800	530	–
	MeCN-d_3	1.53×10^{-3}	–	54400	907	–
5a	NEt_3	1.62×10^{-2}	$1.38 \times 10^{-2} \pm 2.37 \times 10^{-3}$	5975	100	116 ± 16.6
		1.15×10^{-2}		7961	133	
	DCM-d_2	7.81×10^{-3}	–	12000	200	–
	MeCN-d_3	7.61×10^{-4}	$7.39 \times 10^{-4} \pm 2.18 \times 10^{-5}$	112000	1867	1925 ± 58.3
		7.17×10^{-4}		119000	1983	

The raw data sets of the kinetic measurements are summarized in Table 4.24 – Table 4.27.

Table 4.24. Raw data of absolute kinetic of acylation reaction with DMAP (1) in DCM-d₂.

4.4.6 Simulation of Kinetic Experiments – Acylation with Benzoic Anhydride

Kinetic measurements performed with benzoic anhydride were prepared and analyzed according to the procedure described in Chapter 4.3.2 and Chapter 4.3.3. In this benchmark reaction other proton signals were used for the analysis. Figure 4.4 exemplary shows an ^1H -NMR spectrum of the acylation reaction catalyzed by salt **6a**. Proton shift used in the evaluation are marked.

Figure 4.4. NMR spectra of acylation benchmark reaction with benzoic anhydride **19** catalyzed by salt **6a** with assigned ^1H shift necessary of analysis.

The resulting effective reaction rates k_{eff} and half-life times $t_{1/2}$ (min) are summarized in Table 4.28.

Table 4.28. Effective reaction rates k_{eff} ($\text{M}^{-1} \text{s}^{-1}$) and half-life times $t_{1/2}$ (min) for the acylation of 1-ethynylcyclohexanol **16** with benzoic anhydride **19** in CDCl_3 .

$ \begin{array}{c} \text{H} \\ \\ \text{Cyclohexyl-C} \equiv \text{C} \\ \\ \text{OH} \end{array} + \begin{array}{c} \text{O} \quad \text{O} \\ \quad \\ \text{Ph}-\text{C}-\text{O}-\text{C}-\text{Ph} \end{array} \xrightarrow[\text{CDCl}_3, 23^\circ\text{C}]{\text{cat (5 mol\%), internal standard (0.15 eq), NEt}_3 \text{ (3 eq)}} \begin{array}{c} \text{H} \\ \\ \text{Cyclohexyl-C} \equiv \text{C} \\ \\ \text{O-C(=O)-Ph} \end{array} $

Chapter 5. Reactivity Enhancement of Chiral Lewis Base Catalysts through Ion Pair Formation

Veronika Burger, Stella-Marie Bauer and Hendrik Zipse

Unpublished results.

Autor contributions: Veronika Burger (V.B.) and Hendrik Zipse (H.Z.) conceived the study. Synthetic procedures were performed by V.B. and Stella-Marie Bauer (S.B.). Kinetic and mechanistic studies were performed by S.B. in her master project under the supervision of V.B. Computational studies were performed by V.B.

Additional information: Experimental procedures and kinetic studies of S.B. are omitted here and can be found in “Acylation with 2,2,2-Trichloro-*tert*-butyl chloroformate – Kinetic and Mechanistic Studies”, Master thesis, LMU München (Munich), **2022**.

5.1 Introduction

Pyridine-based organocatalysts represent a large class of Lewis Base catalysts for several organocatalytic transformation reaction.^[1,2] DMAP (**1**) is the best-known catalyst of this class, and its scaffold was widely used as a basic framework for the development of multiple chiral derivatives for stereoselective reactions.^[3–6] These chiral variations of **1** can be divided into three subgroups based on their overall topology (see Chart 5.1).

Chart 5.1. Pyridine-based Lewis base catalysts sorted by topology.

Group **A** positions the chiral element within one of the donor groups of the dialkylamino substituents attached to the C4 position of the pyridine ring. Given the distance between these substituents and the catalytically active pyridine-nitrogen, this approach requires a rather large substituent. Group **B** features a chiral side chain, or an axially chiral ligand attached to the C3 position of the pyridine ring. This brings the chiral information closer the Lewis basic reaction center but may also cause conformational changes in the C4 substituent, potentially leading to a reduced absolute catalytic reactivity. Group **C** attaches the chiral substituent to the C2 position, placing it in close proximity of the catalytic center. However, exactly this closeness is known to significantly reduce the nucleophilic activity pyridines.^[5,6] The main reason for the reduced reactivity lies in the structure of the *N*-acylpyridinium ion **26**, which is formed in the first addition step in the acylation mechanism for pyridine-based catalysts as shown in Figure 5.1.^[2] Ideally it would occupy a planar conformation to maximize the conjugation between the electron donor and the acyl group. C2-Substituents, however, force the acyl group out of plane due to steric interactions, which ultimately destabilizes the acylated intermediate **27**, resulting in a lower reaction by increased activation energy.^[7]

Figure 5.1. Mechanism for acylation of alcohols catalyzed by pyridine-based catalysts, adapted from Denmark *et al.*^[2]

In 1996, Vedejs *et al.* published one of the first chiral DMAP derivatives in organocatalysis with a C2-substituent (Vedejs Cat, **28**).^[8] The catalytic efficiency of **28** is, however, strongly reduced due to the C2-substitution such that a classical stereoselective catalytic process was not observed. Nevertheless, the pyridinium acyl salt of **28** was successfully employed in the stereoselective acylation of secondary alcohol

29 using 2,2,2-trichloro-1,1-dimethylethyl chloroformate (**30**) as acylation reagent to form 1-phenylethyl-2,2,2-trichloro-1,1-dimethylethyl carbonate **31** as product, as shown in Scheme 5.1.

Scheme 5.1. Vedejs' chiral DMAP derivative **28** and its original benchmark reaction.

We already demonstrated that the nucleophilic reactivity of catalysts can be increased by introducing ionic moieties into the scaffold. Therefore, the aim of this study was to investigate the potential enhancement of catalytic activity of chiral Lewis base catalysts with previously low reactivity by transforming them into anionic compounds. For this reason, the Vedejs' catalyst **28** was chosen as scaffold, whereas the *N*-dimethylamino group was to be replaced with a sulfonamide group (see Scheme 5.2).

Scheme 5.2. Proposed chiral pyridinamide ion pairs based on Vedejs' catalyst (**28**).

To achieve this goal, several synthetic strategies were explored to develop a viable procedure for the synthesis of a chiral pyridinamide ion pair (**ved-IP**). The synthesis of chiral DMAP **28** was used as a reference point. However, the first acylation step proved to be challenging. Various methods were employed to introduce the substituent at the C2 position, including direct metalation with organometallic reagents and a milder approach *via* lithium-bromide exchange. When these strategies proved unsuccessful, a radical approach was attempted. Despite these efforts, we have so far had only limited success in developing a viable procedure for the synthesis of a chiral pyridinamide. This chapter provides a detailed account of the attempts conducted and could serve as a foundation for future studies.

5.2 Results and Discussion

5.2.1 Synthesis of Chiral Pyridinamide Derivatives

The original synthesis of Vedejs'^[8] catalyst **28** started with the protection of DMAP using BF_3 etherate, followed by the metalation at the C2-position using lithium tetramethylpiperidine (LiTMP) and subsequent acylation by pivaloyl chloride (PivCl) to synthesize ketone **32** in step **A**. In step **B**, an enantioselective reduction was performed with (-)-diisopinocampheyl chloroborane, yielding (*R*)-alcohol **33**, which was then methylated by using potassium hydride in presence of 18-crown-6 and methyl iodide to obtain Vedejs' catalyst **28** as final product in step **C**, as it is shown in Scheme 5.3.

Scheme 5.3. Vedejs' original three step synthesis.^[8]

Based on this procedure, an initial synthesis plan for the formation of chiral sulfonamide derivatives **ved-IP** was developed, keeping the synthesis steps as close to the original synthesis as possible. The first consideration was the selection of a starting compound that would allow the easy introduction of the sulfonamide group after synthesizing the chiral side arm.

In a first attempt, 4-aminopyridine (**34**) was double protected using sodium hydride and benzyl bromide. The protected product **35** was then subjected to step **A** of Vedejs' original synthesis as depicted in Scheme 5.4. After purification *via* column chromatography, instead of the desired C2-ketone **36**, the starting material was reisolated. A potential reason for the failed metalation might have been residual ethyl acetate (EtOAc) in compound **35**. Substrate **35** was dried in high vacuum over two days. However, the NMR spectra still showed a high content of EtOAc in the sample.

Scheme 5.4. Metalation of 4-dibenzylaminopyridine with tetramethyl piperidine lithium (LiTMP) and subsequent acylation with pivaloyl chloride according to Vedejs^[8]; not successful.

Next, we employed 2-bromo-4-nitropyridine (**37**) as starting compound for the synthesis of ketone **38** (see Scheme 5.5). Instead of direct metalation, a lithium-bromide exchange with *n*-BuLi at -78 °C was attempted, followed by acylation with pivaloyl chloride at -78 °C. The NMR of the crude product showed promising signals. However, only starting material was isolated after column chromatography. Thereafter, a modified procedure from Bolm *et al.*,^[9] consisting of a lithium-bromide exchange with *n*-BuLi at -78 °C, followed by the addition of pivalonitrile and subsequent hydrolysis with dilute sulfuric acid, was attempted. Again, no desired product **38** could be isolated after column chromatography. The high-resolution mass spectrometry (HRMS) analysis of the isolated compound, still showed bromine in the sample, indicating that the lithium-bromide exchange did not occur. This would subsequently have prohibited the acylation.

Scheme 5.5. Metalation of 4-nitropyridine with *n*-butyl lithium, followed by acylation with different reagents; not successful.

Another potential reason why these procedures failed might be the absence of a protected pyridine nitrogen, which could have led to side reactions. To avoid this issue, 4-nitropyridine-*N*-oxide (**39**) was used as the next starting compound (see Scheme 5.6). First, a direct metalation on the C2 position of 4-nitropyridine-*N*-oxide according to Vedejs' original synthesis was attempted, followed by acylation with pivaloyl chloride. The crude NMR of this reaction only showed the signals of the starting material instead of product **40**. Next, 4-nitro-2-bromo-pyridine-*N*-oxide (**41**) was used to undergo a lithium-bromide exchange, followed by acylation with pivaloyl chloride in THF at -78 °C. Here, the crude NMR did not show any aromatic signals, indicating complete degradation of the starting material.

Scheme 5.6. Different metalation conditions for 4-nitropyridine-*N*-oxides **39** and **41**, followed by acylation with pivaloyl chloride; not successful.

Afterwards, Grignard reagents were used instead of lithium reagents, as depicted in Scheme 5.7. 2-Bromo-4-nitropyridine (**37**) was used as the starting material. First, *iso*-propylmagnesium chloride lithium chloride complex (*i*-PrMgCl x LiCl) was utilized for the metal-halogen exchange, followed by transmetalation with copper cyanide di(lithium chloride) complex (CuCN x 2 LiCl) in THF at -40 °C. The subsequent acylation was performed with pivaloyl chloride. In the first attempt, the acylation reagent was directly added to the Grignard solution at -40 °C. In the second attempt, the Grignard solution was added dropwise to a solution of pivaloyl chloride in THF at -40 °C. In both cases, no aromatic signals were detected in the crude NMR, indicating degradation of the pyridine ring during the reaction.

Scheme 5.7. Magnesium-bromide exchange with 2-bromo-4-nitropyridine, followed by transmetalation with copper cyanide and subsequent acylation with pivaloyl chloride; not successful.

The nitro group is a strongly deactivating group, which could explain the lack of product formation under the tested reaction conditions for synthesizing the new derivative C2-ketone **32**. Additionally, instead of focusing on synthesizing the ketone, we attempted to synthesize a derivative of alcohol **33** directly, aiming for an enantioselective separation rather than a stereoselective reduction. Therefore, the next starting compound, 2-bromo-4-chloropyridine (**42**), was used. A modified procedure based on Bolm *et al.*^[9] was performed, using lithium-bromide-exchange and pivalaldehyde for the alcohol formation (see Scheme 5.8). However, the crude NMR did not show any aromatic signals, again indicating the degradation of the pyridine ring.

Scheme 5.8. Metalation of 2-bromo-4-chloropyridine with *n*-BuLi, followed by reaction with pivalaldehyde; not successful.

Next, the procedure by Chopping *et al.*^[10] was given a try. As shown in Scheme 5.9, dimethylamino ethanol (DMAE) was used to form a lithiation reagent *in situ* with *n*-BuLi at -5.0 °C. The mixture was then cooled down to -78 °C before pivalaldehyde was added slowly. Once again, the crude NMR did not show any aromatic signals, indicating degradation of the pyridine ring.

Scheme 5.9. Metalation of 4-chloropyridine with dimethylamino ethanoate/*n*-BuLi and acylation with pivaloyl chloride; not successful.

As an alternative to metalation procedures, the carbonyl group was attempted to be introduced via a Weinreb amide. As depicted in Scheme 5.10, methyl-4-chloropicolinate (**45**) was first hydrolyzed under alkaline conditions. The resulting carboxylic acid **46** was converted into the Weinreb amide **47** using *N,O*-dimethyl hydroxylamine, HATU, and Hünig's base. Subsequently, attempts were made to convert Weinreb **47** into the C2-ketone derivative **48**. However, the desired product **48** was not isolated after column chromatography. Instead, the NMR spectra showed another alkylated product, that was not further characterized.

Scheme 5.10. Weinreb amide synthesis starting with methyl-4-chloropicolinate (**45**), followed by reaction with *tert*-butyl lithium yielding C2-ketone derivative **48**; not successful.

Potentially, chloride might be still too deactivating for a successful synthesis of either a derivative of ketone **32** or a non-chiral derivative of alcohol **33**. Therefore, another starting compound, 4-methoxypyridine (**49**), was tested, as shown in Scheme 5.11. Compound **49** was first subjected to the reaction conditions of the original Vedejs' catalyst synthesis. However, the crude NMR did not show aromatic signals, indicating the degradation of the pyridine ring.

Scheme 5.11. Metalation of 4-methoxypyridine (**49**) with LiTMP and subsequent acylation with pivaloyl chloride according to Vedejs^[8]; not successful

Next, 4-methoxypyridine (**49**) was brominated using the procedure of Bori and Comins,^[11] involving a direct metalation with BuLi-LiDMAE^[12] (see Scheme 5.12). This was followed by bromination with 1,2-dibromo tetrachloroethane to form compound **51**, which was then used in the synthesis of ketone **50**. The bromination was successful, yielding 35 % of brominated product **51**. Subsequently, the procedure of Bolm *et al.*^[9] was followed for the synthesis of ketone **50**, which yielded 12 %. While the reaction needs to be optimized, the formation of the ketone **50** was successful for the first time using another starting compound than DMAP (**1**).

Scheme 5.12. Bromination of 4-methoxypyridine (**49**), followed by lithium-bromide exchange and acylation with pivalonitrile.

However, simultaneously performed test reactions on 4-methoxypyridine **49** to transform the 4-methoxy substituent into a group, that could be converted into the sulfonamide group of the final ionic catalyst were unsuccessful (see Chapter 5.4 for details). Consequently, this synthesis pathway was set aside.

Instead of focusing on acylation *via* organometallic methods, a radical approach using the Minisci reaction type was tested next with 4-cyanopyridine (**52**) as starting material, as shown in Scheme 5.13.^[13,14]

Scheme 5.13. Radical acylation of 4-cyanopyridine.

The Minisci reaction works well for the acylation with phenyl glyoxylic acid, yielding 98 % of product **53**. However, with 3,3-dimethyl-2-oxobutanoic acid, instead of the desired acylation, an alkylation occurred due to the better stabilization of the *tert*-butyl radical compared to the acyl radical. Thus, instead of acylation product **54**, the alkylated product **55** was formed. Nevertheless, this approach could be an alternative for the investigation of future chiral side chain in the Vedejs' catalyst.

The synthesis was continued with the reduction of compound **53**, as shown in Scheme 5.14. First, we attempted the stereoselective reduction using (-)-DIP-Cl, according to Vedejs' original synthesis. After five days, instead of (*R*)-**56**, only the starting material **53** was recovered after column chromatography. Next, a classical reduction with sodium borohydride was performed, yielding 65 % of racemic alcohol rac-**56**. The next step would be a diastereomeric separation of the racemic alcohol by reacting rac-**56** with e.g. (1*S*)-camphanoyl chloride to facilitate a chromatographic separation of the resulting diastereomers.^[9]

Scheme 5.14. Radical acylation of 4-cyanopyridine (**52**), followed by reduction of ketone **53**. Stereoselective reduction with (-)-DIP-Cl was not successful.

Furthermore, the conversion of the nitrile group into, for example, a free amino group has to be tested to confirm the validity of this synthetic plan for the synthesis of an ionic Vedejs' catalyst derivative. Scheme 5.15 shows a potential route.^[15]

Scheme 5.15. Proposed synthesis route to convert 2-(*tert*-butyl)isonicotinonitrile into 2-(*tert*-butyl)pyridin-4-amine.

So far, the task of finding a successful synthesis plan for the preparation of an ionic Vedejs catalyst has not been solved. However, to determine what potential result can be expected, computational studies were performed to: a) identify the most promising sulfonamide substituent to enhance the reactivity of

the chiral pyridinamide ion pair, and b) to assess what reactivity and enantioselectivity can be expected from the ionic Vedejs derivative compared to the original neutral compound **28**.

5.2.2 Computational Study

To examine which chiral pyridinamide derivative should be the focus of our synthetic endeavors, preliminary computational studies regarding their reactivity and stereoinductive potential were performed at the SMD(CHCl₃)/B3LYP-D3/6-31+G(d) level of theory. The strategy of the conformational search is detailed in Chapter 5.4, however, it should be noted that additional studies regarding the procedure should be undertaken to minimize computational costs and effort. Relative affinity values, such as acyl cation affinities (Δ ACA) and methyl cation affinities (Δ MCA), have been shown to correlate well with experimentally obtained rate constants.^[16–18] As shown in Scheme 5.16, acyl cation affinities (Δ ACA) were calculated as reaction enthalpies at 298.15 K of an isodesmic group transfer reaction with pyridine as reference system.

Scheme 5.16. Isodesmic acyl transfer reaction for acyl cation affinity (ACA) calculation between reference pyridine and Vedejs' catalyst **28**.

The Lewis basicity of **28** was lower than that of neutral non-chiral reference organocatalyst DMAP (**1**) due to the deactivating effect of the C2-substituent. Chiral pyridinamide anions **ved-3***, **ved-4***, and **ved-6*** showed a much larger Lewis basicity despite carrying the same C2-substituent. However, looking at the respective chiral ion pair **ved-3a*** the Lewis basicity was reduced by a factor of two. Applying this factor to pyridinamide anion **ved-4*** and **ved-6***, the Lewis basicity of their respective ion pair can be expected to be located in the region around -50 to -60 kJ mol⁻¹. Even so, **ved-3a*** surpassed **28** in terms of relative Lewis basicity towards the acyl group. Therefore, a higher reactivity can be expected, which would fulfill the first aim of this study: the enhancement of chiral Lewis base catalysts through ion formation.

Figure 5.2. Acyl cation affinity values (Δ ACA) of DMAP (**1**), Vedejs catalyst (**28**), chiral pyridinamide ion pair **3a***, and chiral pyridinamide anion **ved-3***, **ved-4***, and **ved-6***.

The enhancement of reactivity is only useful if the selectivity of the new chiral pyridinamide catalyst remains the same or improves. To predict the stereo-inductive potential of chiral pyridinamide ion pair derivatives, a modified version of Mosher's cation approach, first introduced as a chirality prediction tool by Zipse *et al.*^[19] in 2008, was used. Previously, the Mosher's cation fragment **57** was attached directly to the catalytic center of the chiral compound, once in (*R*)-configuration and once in (*S*)-configuration. In

this work, the carbonyl group of Mosher's acid was included in the chiral fragment **58** and the chiral adducts to maintain a closer representation of the experimental conditions (see Scheme 5.17A).

Scheme 5.17. A) Simplified model reaction of Mosher's cation affinity (MOCA) calculation. B) Exemplary isodesmic Mosher's cation transfer reaction for calculation of Mosher's cation affinity values (ΔMOCA).

The Mosher's cation affinity was then calculated as the reaction enthalpy of an isodesmic group transfer reaction with pyridine as reference compound as shown in Scheme 5.17B. Subtracting the resulting affinity values $\Delta\text{MOCA}(R-S)$ supposedly indicates which enantiomer will be preferred.

Figure 5.3. Mosher's cation affinity values ($\Delta\text{MOCA}(R-S)$) of Vedejs' catalyst (**28**) and chiral pyridinamide anion **3***, **4***, and **6***.

The preliminary results for the ΔMOCA of the chiral pyridinamide anions indicated a preference for the *S*-configuration for chiral anion **ved-3***, whereas chiral anions **ved-4*** and **ved-6*** clearly favor the *R*-configuration. Vedejs *et al.* reported the enantiomeric purity of the *S*-enantiomer of the ester product to be greater than 90 % at conversions in the 20–40 % range.^[8] Thus, even with a strongly reduced reactivity, the loaded pyridinium salt of the catalyst displayed a high stereoselectivity. This clear preference for the *S*-configuration of the ester product was not evident in the $\Delta\text{MOCA}(R-S)$ of the Vedejs' catalyst. These findings tell us that this ΔMOCA approach to quantify the stereo-inductive potential of catalysts does not provide reliable results as it stands.

5.3 Conclusion & Outlook

The synthesis of chiral pyridinamide derivatives posed significant challenges, especially when adapting Vedejs' original synthesis for various 2-substituted pyridine derivatives. Metalation and subsequent acylation, particularly with strongly deactivating groups, such as nitro group and chloro group at the C4 position, repeatedly failed. Despite various attempts, including alternative approaches, such as lithium-bromide exchange and Grignard reagents, the successful synthesis of derivatives of ketone **32** or alcohol **33** was only achieved in the low-yield synthesis of 1-(4-methoxypyridin-2-yl)-2,2-dimethylpropan-1-one (**50**) starting from 4-methoxypyridine (**49**). The exploration of the Minisci reaction for radical acylation proved to be a potential alternative, although the stereoselective reductions have not been successful, so far. Classical reduction methods, however, showed promising results and, in combination with diastereomeric separation of enantiomers, could lead to potential future ionic Vedejs' catalyst derivatives.

Computational studies aimed at predicting the reactivity and stereoselectivity of chiral pyridinamide derivatives yielded mixed results, indicating the need for refined methods to improve their predictive accuracy.

Future efforts in this area should focus on finding a synthetic route for chiral ionic Vedejs derivatives. The Minisci reaction might be a viable alternative for the acylation step if a phenyl group instead of a *tert*-butyl group is an acceptable alternative. However, the transformation of the nitrile group might still prove to be problematic. Particular attention should be paid to the protection of the pyridine nitrogen in future reactions as this may be a reason for the repeated failures. Suitable protection strategies would be the use of *N*-oxide derivatives as starting materials or to protect the pyridine *N* with BF_3 , as done by Vedejs, or BH_3 , as done by other researchers.^[8,20]

An alternative strategy could be the synthesis of 2-cyano-4-chloropyridine, followed by conversion of the cyano group to the pivaloyl group with an organometallic reagent, such as *t*-BuLi or *t*-butylmagnesium bromide, which could be hydrolyzed to the corresponding acyl group.^[21,22] Subsequent stereoselective reduction and methylation would be done according to Vedejs' procedure. The transformation of the 4-chloro substituent could be done with a Buchwald-Hartwig reaction, followed by the final ion pair synthesis.

5.4 Supporting Information

5.4.1 Experimental Data

5.4.1.1 General

All reactions sensitive to air and moisture were performed in dried glassware under nitrogen atmosphere, if not stated otherwise. All reagents were purchased from Sigma Aldrich, TCI or Acros and used without further purification, unless otherwise noted. All air and water sensitive reagents were stored under nitrogen. Solvents were obtained from Acros Organics, Sigma Aldrich, or Merck and purified by simple distillation in a rotary evaporator, unless otherwise specified.

Silica gel for column chromatography was purchased from Acros Organics (mesh 35-70). Thin-layer chromatography was performed by using TLC plates purchased from Merck (silica gel 60 F254, thickness 0.2 mm).

Nuclear magnetic resonance (NMR) spectra were recorded on Bruker 400 MHz or an INOVA 400 and 600 MHz machines. The following abbreviations were used in the analysis of NMR spectra: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, br s = broad singlet. NMR signals were assigned based on 2D spectra (COSY, HSQC, HMBC, NOESY) experiment analysis. Chemical shifts were given in ppm. The internal reference was set to the residual solvent signals (CDCl₃). The ¹³C NMR spectra (101 or 151 MHz) were recorded under broadband proton-decoupling. The spectra were imported and processed in the program MestreNova (version 14.1.1 and 14.3.2).

5.4.1.2 Synthetic Procedures

N,N-dibenzylpyridin-4-amine (35)

A solution of 4-aminopyridine (500 mg, 1.0 eq) in THF (10.0 mL) at 35 °C was treated with NaH (2.2 eq) in small portions and stirred for 1.5 h. Thereafter, benzylbromide (2.2 eq) was added and the mixture was heated to 70 °C for 4 h. The mixture was hydrolyzed with saturated aqueous solution of NH₄Cl (8.0 mL). The volatile solvent was evaporated, and the residue was extracted with EtOAc (2 x 20 mL). The organic layer was washed with water (1 x 20 mL) and brine (1 x 20 mL). Then, the organic layer was dried with MgSO₄, filtered and the solvent was evaporated. After purification by column chromatography (EtOAc + 1% NEt₃) product **35** (195 mg, 15 %) was isolated as yellowish oil.

¹H NMR (400 MHz, CDCl₃): δ [ppm] = 8.22 – 8.15 (m, 2 H), 7.39 – 7.28 (m, 6 H), 7.20 (dd, *J* = 6.9, 1.8 Hz, 4 H), 6.61 – 6.52 (m, 2 H), 4.66 (s, 4 H).

1-(4-(dibenzylamino)pyridin-2-yl)-2,2-dimethylpropan-1-one (36) (not successful)

Following Vedejs' synthetic procedure^[8], *N,N*-dibenzylpyridin-4-amine (195 mg, 1.0 eq) was dissolved in dry THF (3.0 mL) and cooled to 0 °C before BF₃ etherate (1.06 eq) was added. The mixture was stirred at 0 °C for 30 min. In a second flask, 2,2,2,2-tetramethyl piperidine (TMP, 110 mg, 1.0 eq) in dry THF (2.0 mL) at -78 °C was treated with *n*-BuLi (1.10 eq) before the solution was warmed to rt. The protected *N,N*-dibenzylpyridin-4-amine solution was cooled to -78 °C before the LiTMP solution was added via syringe. The resulting orange solution was stirred at -78 °C for 30 min. In a third flask, pivaloyl chloride (2.0 eq) in dry THF (3.0 mL) was cooled to -78 °C before the previously prepared solution was added dropwise. The combined mixture was stirred at -78 °C for 5 h before being allowed for warm up to rt. Water (2.0 mL), MeOH (2.0 mL), and 6 N HCl (2.0 mL) were added sequentially, and the mixture was stirred at 38 °C overnight. The volatile solvents were removed, the residue was brought to pH = 9 with 2 N NaOH and extracted with diethyl ether (1 x 15 mL) and EtOAc (2 x 20 mL). The organic phase was washed with

brine (1 x 20 mL) and dried over MgSO_4 before evaporation. Purification was attempted with column chromatography ($\text{EtOAc} + 1\% \text{NEt}_3$), only starting material was isolated.

2,2-dimethyl-1-(4-nitropyridin-2-yl)propan-1-one (**38**) (not successful)

2-Bromo-4-nitropyridine (315 mg, 1.0 eq) was treated with *n*-BuLi (1.1 eq) in dry THF (6.0 mL) at -78°C and stirred for 1 h. Pivaloyl chloride (2.0 eq) was added dropwise at -78°C . The reaction mixture was stirred at -78°C for 5 h before it was allowed to warm to rt. 6 N HCl (2 mL) and water (4.0 mL) were added, stirred for 30 min, and the two phases were separated. The aqueous phase was brought to pH = 9 with 2 M NaOH and extracted with Et_2O (3 x 15 mL), dried over MgSO_4 before evaporating the solvent. Purification was attempted with column chromatography ($n\text{-Hex}/\text{EtOAc} = 5/1$, + 5% NEt_3), however only starting material was reisolated.

In a second attempt, 2-bromo-4-nitropyridine (321 mg, 1.0 eq) was treated with *n*-BuLi (1.1 eq) in dry THF (3.0 mL) at -78°C and stirred for 1.5 h. In a second flask, pivaloyl chloride (1.3 eq) in dry THF (3.0 mL) was cooled to -78°C and the mixture of flask 1 was added dropwise over 30 min. The combined reaction solution was stirred at -78°C for 5 h before being allowed to reach rt. Water (2.0 mL), MeOH (1.0 mL), and 6 N HCl (2.0 mL) were added sequentially at 0°C and stirred for 30 min. After phase separation, the aqueous solution was extracted with Et_2O (3 x 15 mL) and THF (1 x 15 mL), dried over MgSO_4 and evaporated. Purification was attempted with column chromatography ($n\text{-Hex}/\text{EtOAc} = 8/1 \rightarrow 7/1 \rightarrow 5/1 \rightarrow 1/2 \rightarrow 0/1 + 1\% \text{NEt}_3$), however only starting material was obtained.

Following a procedure adapted from Bolm *et al.*^[9], 2-bromo-4-nitropyridine (305 mg, 1.0 eq) was treated with *n*-BuLi (1.1 eq) in dry Et_2O (6.0 mL) at -78°C and stirred for 30 min. Pivalonitrile was added dropwise and stirred for 1.5 h at -78°C before the mixture was allowed to reach rt. Then, 2 N H_2SO_4 (5.1 mL) was added, the mixture was refluxed for 2 h, and then stirred at 30°C overnight. After cooling down to rt. Et_2O was added and the aqueous layer was brought to pH = 9 with 2 N NaOH and extracted with Et_2O (3 x 15 mL), dried with MgSO_4 and evaporated. Purification was attempted with column chromatography ($n\text{-Hex}/\text{EtOAc} = 2/1$), no desired product was isolated.

2-Bromo-4-nitropyridine (225 mg, 1.0 eq) in dry THF (5.5 mL) at -40°C was treated with *i*-PrMgCl x LiCl (1.1 eq) at stirred for 1.5 h. $\text{CuCN} \times 2 \text{LiCl}$ (1.1 eq) was added and resulting mixture was stirred for another 30 min at -40°C before pivaloyl chloride (1.1 eq) was added. The mixture was stirred at -40°C for 30 min before being allowed to warm to rt. Subsequently, it was stirred at rt. overnight before adding aqueous ammonium chloride solution (4.0 mL) and 2 N NH_3 (1.0 mL). After phase separation, the aqueous layer was extracted with Et_2O (3 x 15 mL). The combined organic phases were dried over MgSO_4 , filtered and the solvent was evaporated. Purification was attempted with column chromatography ($n\text{-Hex}/\text{EtOAc} = 5/1 + 5\% \text{NEt}_3 \rightarrow 1/1$), no desired product was isolated.^[23]

The reaction was repeated with 2-bromo-4-nitropyridine (201 mg, 1.0 eq) in dry THF (5.0 mL) at -40°C . The mixture was treated with *i*-PrMgCl x LiCl (1.1 eq) and stirred for 15 min. Subsequently, $\text{CuCN} \times 2 \text{LiCl}$ (1.1 eq) was added, and the resulting mixture was stirred for an additional 45 min at -40°C . Thereafter, mixture was added to a solution of pivaloyl chloride (1.0 eq) in dry THF (2.0 mL) at -40°C . The mixture was stirred at -40°C for 3 h before being allowed to slowly warm to rt overnight. Then, aqueous ammonium chloride solution (4.0 mL) and 2 N NH_3 (1.0 mL) was added. Following phase separation, the aqueous layer was extracted with Et_2O (3 x 15 mL). The combined organic phases were dried over MgSO_4 , filtered, and the solvent was evaporated. The crude NMR exhibited no aromatic signals, indicating the degradation of the pyridine ring.

4-nitro-2-pivaloylpyridine 1-oxide (40) (not successful)

2-Bromo-4-nitropyridine-1-oxide (306 mg, 1.0 eq) in dry THF (5.0 mL) was treated with *n*-BuLi (1.1 eq) at -78 °C and stirred for 40 min. In a second flask, pivaloyl chloride (1.8 eq) in dry THF (5.0 mL) was cooled to -78 °C and the mixture of flask 1 was added dropwise over a period of 30 min. The combined reaction solution was stirred at 78 °C for 4 h, after which it was allowed to warm to rt. and stirred further overnight. Next, 2 M HCl (2.0 mL) and water (2.0 mL) was added at 0 °C. Following phase separation, the aqueous phase was adjusted to pH = 9 with 2 M NaOH and extracted with Et₂O (3 x 15 mL). The combined organic layer was then dried over MgSO₄, filtered and the solvent was evaporated. The crude NMR showed only weak shifts of the starting material.

In a second attempt, TMP (1.1 eq) in dry THF (3.0 mL) at -78 °C was treated with *n*-BuLi (1.1 eq) and stirred for 30 min before it was allowed to warm to rt. A solution of 4-nitropyridine-1-oxide (401 mg, 1.0 eq) in dry THF (3 mL) at -78 °C was treated with the LiTMP solution and stirred for 30 min. In a third flask, pivaloyl chloride (1.3 eq) in dry THF (5.0 mL) at -78 °C was treated with the previously prepared reaction mixture. The final reaction mixture was stirred at -78 °C for 4 h before it was warmed to rt. Thereafter, 2 M HCl (2.0 mL), water (2.0 mL), and MeOH (2.0 mL) was added at 0 °C and stirred for 30 min. After addition of water, the phases were separated, and the aqueous layer was adjusted to pH = 9 with 2 M NaOH. Subsequently, it was extracted with Et₂O (1 x 15 mL) and EtOAc (2 x 20 mL). The organic layer was dried over MgSO₄, filtered and the solvent was evaporated. The crude NMR showed only shifts of the starting material.

1-(4-chloropyridin-2-yl)-2,2-dimethylpropan-1-ol (43) (not successful)

An adapted procedure of Bolm's et al.^[9] was followed. Therefore, 2-bromo-4-chloropyridine (393 mg, 1.0 eq) in dry THF (10.0 mL) at -78 °C was treated with *n*-BuLi (1.1 eq) and stirred for 1 h. Pivalaldehyde (1.5 eq) was added at -78 °C and the solution was stirred for 1.5 h before it was allowed to warm to rt. After stirring for 1 h, the mixture was cooled to 0 °C and treated with water (10.0 mL). After phase separation, the aqueous layer was extracted with DCM (3 x 15 mL). The combined organic layers were dried over MgSO₄, filtered and the solvent was evaporated. The crude NMR did not show aromatic signals, indicating the degradation of the pyridine ring.

The starting material was gained by dissolving 4-chloropyridine hydrochloride (510 mg) in water (pH = 2) and adjusting the pH to pH = 9 with aqueous K₂CO₃ solution at 0 °C. DCM was added and stirred for 30 min. After phase separation, the aqueous layer was extracted with DCM (3 x 10 mL). The organic layer was dried over MgSO₄, filtered and the solvent was evaporated at rt. using a rotary evaporator, yielding 4-chloropyridine (265 mg, 69%).

Next, a procedure by Choppin *et al.*^[10] was followed. 2-Dimethylaminoethanol (DMAE, 4.0 eq) in dry *n*-hexane (5.0 mL) at -4 °C was treated with *n*-BuLi (8.0 eq) and stirred for 30 min. After cooling to -78 °C, a solution of neutralized 4-chloropyridine (250 mg, 1.0 eq) in *n*-hexane (5.0 mL) was added dropwise. After stirring for 1 h, the solution was treated with a solution of pivalaldehyde in *n*-hexane (20 mL) at -78 °C. The reaction mixture was then allowed to warm slowly to rt. and was then hydrolyzed with water (20 mL) at 0 °C. The aqueous layer was extracted with DCM (3 x 15 mL). The organic layer was dried over MgSO₄, filtered and the solvent was evaporated. The crude NMR did not show aromatic signals, indicating the degradation of the pyridine ring.

Methyl 4-chloropicolinate (**45**) (502 mg, 1.0 eq) in THF/MeOH (1:1; 28 mL) was treated with 2M NaOH (1.1 eq) and stirred at rt. overnight. Thereafter, 1 M potassium bisulfate (KHSO₄, 1.0 eq) was added. The mixture was extracted with EtOAc (3 x 50 mL). The organic layer was washed with brine (1 x 50 mL), dried over MgSO₄, and filtered. Evaporation of the solvent yielded 4-chloropicolinic acid **46** (355 mg, 77%) as off-white solid.

¹H NMR (400 MHz, DMSO-*d*₆): δ [ppm] = 13.57 (s, 1 H), 8.68 (d, *J* = 5.3 Hz, 1 H), 8.06 (d, *J* = 2.2 Hz, 1 H), 7.80 (dd, *J* = 5.3, 2.1 Hz, 1 H).

A solution of 4-chloropicolinic acid (**46**) (355 mg, 1.0 eq) in DMF (3.5 mL) was treated with HATU (1.5 eq), amin (1.5 eq) and Hünig base (3.0 eq) at rt and stirred overnight. After addition of aqueous NaHCO₃ (25.0 mL), the mixture was extracted with EtOAc (3 x 25 mL). The combined organic layers were washed with water (3 x 50 mL) and brine (1 x 40 mL) and dried over MgSO₄. The solvent was evaporated, and the crude product was purified with column chromatography (Hex/EtOAc = 1:1) yielding 4-chloro-*N*-methoxy-*N*-methylpicolinamide **47** (246 mg, 55%) as off-white solid.^[24]

¹H NMR (400 MHz, CDCl₃): δ [ppm] = 8.52 (d, *J* = 5.3 Hz, 1 H), 7.66 (s, 1 H), 7.37 (dd, *J* = 5.3, 2.1 Hz, 1 H), 3.75 (s, 3 H), 3.40 (s, 3 H).

A solution of 4-chloro-*N*-methoxy-*N*-methylpicolinamide (**47**) (245 mg, 1.0 eq) in Et₂O (6.0 mL) at -78 °C was treated slowly with *t*-BuLi (1.1 eq). After 1 h, the mixture was allowed to warm to rt. and aqueous NH₄Cl (5.0 mL) was added. The aqueous layer was extracted with Et₂O (3 x 10 mL). The organic layer was dried over MgSO₄, filtered and the solvent was evaporated. Purification was attempted with column chromatography (*n*-Hex/EtOAc = 5/1 → 3/1 → 1/1), product **48** could not be isolated.

1-(4-methoxypyridin-2-yl)-2,2-dimethylpropan-1-one (**50**) (not successful)

Following a modified procedure from Vedejs *et al.*, 4-methoxypyridine (300 mg, 1.0 eq) in THF (1.0 mL) at 0 °C was treated with BF₃ etherate (1.06 eq) and stirred for 30 min. A solution of TMP (1.06 eq) in dry THF (4.0 mL) at -78 °C was treated with *n*-BuLi (1.1 eq) before the solution was slowly warmed to rt. The protected 4-methoxypyridine solution was treated with the LiTMP solution at -78 °C and stirred for 30 min. In a third flask, pivaloyl chloride (2.0 eq) in dry THF (3.0 mL) was cooled to -78 °C and treated with the previously prepared reaction mixture. The combined solution was stirred at -78 °C for 4 h before being allowed for warm up to rt. Water (2.0 mL), MeOH (2.0 mL), and 6 N HCl (2.0 mL) were added sequentially, and the mixture was stirred overnight. The volatile solvents

were removed (rotary evaporator), the residue was brought to pH = 9 with 2 N NaOH and extracted with diethyl ether (1 x 15 mL) and EtOAc (2 x 20 mL). The organic phase was washed with brine (1 x 20 mL) and dried over MgSO₄ before evaporation. The crude NMR did not show aromatic signals, indicating the degradation of the pyridine ring.

1-(4-methoxypyridin-2-yl)-2,2-dimethylpropan-1-one (**50**) (successful)

A solution of DMAE (2.0 eq) in dry THF (2.6 mL) at -20 °C was treated with *n*-BuLi (4.0 eq) and stirred for 30 min. 4-Methoxypyridine (200 mg, 1.0 eq) was added and the solution was cooled to -78 °C. A solution of 1,2-dibromo-1,1,2,2-tetrachloroethane (2.4 eq) in dry THF (2.3 mL) was added and mixture was stirred in the cooling bath to slowly warm up overnight. Thereafter, the solution was hydrolyzed with water (6.0 mL) at 0 °C. The aqueous layer was extracted with Et₂O (3 x 15 mL) and DCM (1 x 10 mL). The organic layer was dried over MgSO₄, filtered and the solvent was evaporated yielding 2-bromo-4-methoxypyridine **51** (124 mg, 35 %).^[11]

¹H NMR (400 MHz, CDCl₃): δ [ppm] = 8.18 (dd, *J* = 8.8, 5.8 Hz, 1H), 6.92 (dd, *J* = 65.3, 2.3 Hz, 1H), 6.77 (ddd, *J* = 11.2, 5.8, 2.3 Hz, 1H), 3.85 (s, 2H).

Following a procedure adapted from Bolm *et al.*^[9], 2-bromo-4-methoxypyridine (94.0 mg, 1.0 eq) in dry THF (2.0 mL) at -78 °C was treated with *n*-BuLi (1.1 eq) and stirred for 45 min. Pivalonitrile was added dropwise and stirred at -78 °C for 1 h, before the mixture was allowed to reach rt. After addition of 2 N H₂SO₄ (1.4 mL), the mixture was refluxed for 2 h (60 °C oil bath). After cooling down to rt. Et₂O was added and the aqueous layer was extracted with Et₂O (3 x 15 mL). The organic layer was dried over MgSO₄, filtered and the solvent was evaporated. Purification was performed with column chromatography (*n*-Hex/EtOAc = 6/1), yielding 1-(4-methoxypyridin-2-yl)-2,2-dimethylpropan-1-one **50** (11.7 mg, 12 %).

¹H NMR (400 MHz, CDCl₃): δ [ppm] = 8.42 (d, *J* = 5.6 Hz, 1 H), 7.40 (d, *J* = 2.6 Hz, 1 H), 6.88 (dd, *J* = 5.6, 2.6 Hz, 1H), 3.87 (s, 3 H), 1.44 (s, 9 H).

¹³C NMR (101 MHz, CDCl₃): δ [ppm] = 207.1, 166.4, 156.8, 149.2, 112.6, 109.0, 55.4, 44.4, 27.6.

N,N-dibenzylpyridin-4-amine (**35**) (not successful)

Following a procedure from Wang *et al.*, *N,N*-dibenzylamine (1.6 eq) in dry THF (1.0 mL) at -78 °C was treated with *n*-BuLi (1.76 eq). The mixture was stirred for 10 min at rt. 4-Methoxypyridine (54.5 mg, 1.0 eq) was added and the mixture was stirred at 60 °C for 1 h. Thereafter, the mixture was cooled down to rt., hydrolyzed with water (6.0 mL), and then extracted with DCM (3 x 10 mL). The organic layer was dried with MgSO₄, filtered and the solvent was evaporated. Purification was attempted with column chromatography (EtOAc + 1 % NEt₃), however, no product was found.

General acylation procedure for 4-cyanopyridine (adapted from Fontanta *et al.*^[14])

4-Cyanopyridine (1.0 eq) with the respective α-keto acid (3.0 eq), AgNO₃ (0.1 eq), NH₄S₂O₈ (3.0 eq), and H₂SO₄ or trifluoroacetic acid (TFA) was added to a DCM/water mix (25 mL each) and stirred at 40 °C for 2 h. After cooling down to rt., the aqueous layer was extracted with DCM (3 x 20 mL). The organic layer was dried with MgSO₄, filtered

over celite and the solvent was evaporated. The crude product was purified with column chromatography (hex/EtOAc = 5/1).

2-Benzoylisonicotinonitrile (**53**)

4-Cyanopyridine (1.00 g, 1.0 eq), 2-oxo-2-phenylacetic acid (3.0 eq), AgNO₃ (0.1 eq), NH₄S₂O₈ (3.0 eq), and H₂SO₄ (1.0 eq) were reacted according to the general acylation procedure. After purification by column chromatography (hex/EtOAc = 5/1), **53** (1.94 g, 97 %) was obtained as an off-white solid.

¹H NMR (400 MHz, CDCl₃): δ [ppm] = 8.91 (dd, *J* = 5.0, 0.9 Hz, 1 H), 8.28 (dd, *J* = 1.6, 0.9 Hz, 1 H), 8.11 – 8.05 (m, 2 H), 7.72 (dd, *J* = 5.0, 1.6 Hz, 1 H), 7.68 – 7.62 (m, 1 H), 7.55 – 7.46 (m, 2 H).

¹³C NMR (101 MHz, CDCl₃): δ [ppm] = 191.77, 156.27, 149.59, 135.29, 133.78, 131.18, 128.53, 127.40, 126.53, 122.05, 116.01.

2-Pivaloylisonicotinonitrile (**55**)

4-Cyanopyridine (300 mg, 1.0 eq), 3,3-dimethyl-2-oxobutanoic acid (3.0 eq), AgNO₃ (0.1 eq), NH₄S₂O₈ (3.0 eq), and TFA (1.0 eq) were reacted according to the general acylation procedure. After purification by column chromatography (hex/EtOAc = 5/1), instead of the wanted acylation product 2-pivaloylisonicotinonitrile, the alkylation product 2-(*t*-butyl)isonicotinonitrile (302 mg, 56 %) was isolated as an off-white solid.

¹H NMR (400 MHz, CDCl₃): δ [ppm] = 8.73 (d, *J* = 5.0 Hz, 1 H), 7.55 (s, 1 H), 7.32 (dd, *J* = 4.9, 1.6 Hz, 1 H), 1.37 (s, 9 H).

¹³C NMR (101 MHz, CDCl₃): δ [ppm] = 171.2, 149.8, 122.2, 121.2, 120.60, 117.3, 38.1, 30.0.

(*R*)-2-(hydroxy(phenyl)methyl)isonicotinonitrile (**R-56**) (not successful)

To a solution of (-)-DIP chloride (1.5 eq) in dry THF (5.0 mL) at rt. 2-benzoylisonicotinonitrile (500 mg, 1.0 eq) was added and stirred vigorously for 5 d. Thereafter, diethanolamine (1.0 mL), MeOH (2.0 mL), water (2.5 mL), and conc HCl (1.0 mL) was added, and the mixture was heated to 40 °C for 4 h. EtOAc was added and the phases were separated. The organic layer was washed with 2 N HCl (2 x 20 mL). The combined aqueous layer was adjusted to pH = 9 with 2 N NaOH and extracted with EtOAc (2 x 20 mL). The combined organic layer was dried with MgSO₄, filtered and the solvent was removed. After purification by column chromatography (hex/EtOAc = 5/1) the starting material (90 %) was recovered.

2-(hydroxy(phenyl)methyl)isonicotinonitrile (rac-**56**)

2-benzoylisonicotinonitrile (498 mg, 1.0 eq) was dissolved in ample dry MeOH and EtOH (approx. 25.0 mL). After addition of sodium borohydride (NaBH₄, 0.3 eq), the mixture was stirred at rt. for 4 h. Water (10.0 mL) and DCM (10.0 mL) were added at 0 °C. The volatile solvents were removed, and the residue was extracted with DCM (3 x 15 mL). The organic layer was dried with MgSO₄, filtered and the solvent was evaporated. After purification by column chromatography (hex/EtOAc = 1/1) product rac-**56** (327 mg, 65 %) was isolated as yellowish oil.

¹H NMR (400 MHz, CDCl₃): δ [ppm] = 8.74 (d, *J* = 5.1 Hz, 1 H), 7.49 (s, 1 H), 7.43 (d, *J* = 5.0 Hz, 1 H), 7.40 – 7.30 (m, 5 H), 5.83 (s, 1 H), 4.49 (s, 1 H).

¹³C NMR (101 MHz, CDCl₃): δ [ppm] = 171.3, 163.2, 149.3, 141.9, 129.1, 128.6, 127.1, 124.0, 123.2, 121.4, 116.5, 75.4.

5.4.2 Computational Data

Calculation Method. Geometry optimization and vibrational frequency calculations were performed using the B3LYP-D3 hybrid function^[25–27] in combination with the 6-31+G(d) basis set.^[28] Chloroform solvation effects were allowed for with the SMD continuum solvation model.^[29] This combination has been found to perform well for the description of charge-separated intermediates.^[30,31] Thermochemical corrections to 298.15 K have been calculated for all minima from unscaled vibrational frequencies obtained at this same level. All calculations have been performed using Gaussian 09.^[32]

Conformer generation. For the ion pair catalysts, the conformers of the single tetraphenylphosphonium cations were obtained from a former group member. Conformers for single anion **1** were generated with Maestro^[33] using a 30 to 50 kJ/mol energy window to obtain a good conformational coverage. For the final ion pair the six best anion conformers (15 kJ/mol energy window) were taken and combined with the best cation conformer by using the stochastic kick procedure invented by Saunders^[34] and further developed by Sakic^[35] to generate 20 new conformers per starting point. This resulted in 120 new ion pair conformers for which geometry optimization and vibrational frequency calculations were performed.

Conformer generation for acylated catalyst adducts. For each of the obtained neutral catalysts was manually generated two acetyl adducts in the plane of the pyridine ring in Gauss View and geometry optimization and vibrational frequency calculations were performed. For the ion pair derivatives, the 10 best conformers were manually acylated to generate two acetyl adducts, whereas the acetyl group was drawn in a 90° and 180°, respectively, towards the pyridine ring in Gauss View. Subsequently, geometry optimization and vibrational frequency calculations were performed.

Conformer generation for Mosher's acid cation catalyst adducts. For the Vedejs-based ion pair derivatives the conformers of the anions were generated with Maestro^[33] using a 50 kJ/mol energy window. For each generated conformer, however, a two-step optimization (MaxCycles=2) at the SMD (CHCl₃)/B3LYP-D3/6-31+G(d) level of theory was performed. The conformers were sorted according to their energies and the best conformers in a 40 kJ/mol window were selected for a full geometry optimization and vibrational frequency calculations. No conformer had to be excluded before the 40 kJ/mol window was established.

Following the geometry optimization and frequency calculation, acyl cation affinities were calculated as Lewis basicity parameter relative to pyridine as reference system. The relative Lewis basicity towards the acyl-cation was calculated as the reaction enthalpy at 298.15 K in the isodesmic group transfer reaction shown in Scheme 5.18.

Scheme 5.18. Acyl Cation Affinity (ACA) model between reference pyridine and the calculated Vedejs catalysts derivatives with R* being the chiral substituent.

Another descriptor that was investigated is the “Mosher's cation affinities” (MOCA) to describe chirality of the catalyst. In theory, the reaction of “Mosher's cation” (MOC, Scheme 5.19a) with a chiral compound can occur from either the *re* or the *si* side of the cation, yielding to diastereomeric adducts with two different affinity values: MOCA(R) and MOCA(S). The originally proposed procedure for MOCA calculations was slightly modified.^[19] Instead of calculating the reaction of the catalyst with the chiral Mosher's acid fragment, the chirality descriptor was calculated as the reaction enthalpy at 298.15 K in the isodesmic group transfer reaction shown in Scheme 5.19. Pyridine was chosen as reference compound and the Mosher's acid was added as chiral acyl group.

Scheme 5.19. A) Mosher's acid with (*R*) and (*S*) stereochemistry. B) Mosher's acid cation affinity (MOCA) model for pyridine-derived catalysts with a (*R*) stereochemistry for the Mosher's adduct and C) with a (*S*) stereochemistry, calculated at the SMD(CHCl₃)/B3LYP-D3/6-31+G(d) level of theory.

The resulting affinity values are summarized in Table 5.1.

Table 5.1. Summary of acyl cation affinities and Mosher's cation affinities of

Chapter 6. Conclusion and Outlook

Pyridine-based Lewis base catalysts represent a large and extensively studied group of organocatalysts.^[1,2] The first significant discovery in this field was the synthesis of dimethylamino pyridine (DMAP) in 1967.^[3,4] Subsequent developments were the introduction of 4-pyrrolidine (PPY)^[5] and 9-azajulolidine (TCAP),^[6] pushing the boundaries of catalytic activity. Since then, based on the success of TCAP, numerous donor-substituted organocatalysts have been developed with the aim to further enhance the catalytic activity. Recently, Helberg and Zipse^[7] presented an overlooked strategy to increase the electron density of the pyridine ring by employing stabilized 4-pyridinamide anions. These pyridinamide ion pairs display an enhanced reactivity in the urethane reaction of isocyanates with 1-butanol and in *aza*-Morita-Baylis Hillman reactions. However, studying ionic substrates requires a new methodological approach to gain insights into their unique reactivity.

In this study, an analytical protocol was developed to facilitate insights into the concentration of specific ions, their association patterns, and the nucleophilicity of the anions involved. A combination of conductivity, diffusion-ordered (DOSY) NMR, and kinetic measurements was employed to study the complex association behavior of pyridinamide ion pairs in organic solvents of low polarity and its impact on catalytic performance. With the combination of conductivity and DOSY measurements, an asymmetric association pattern of cationic and anionic triple sandwich complexes with the corresponding free counterion in organic solvents of low polarity such as dichloromethane (DCM), was deciphered. Without this combination of conductivity and DOSY measurements, this result would have been impossible, as conductivity alone does not reveal insights on the type of charged species being measured. The association pattern is strongly influenced by the size and structure of the cation, which affects the balance between cationic and anionic sandwich association. The association constants of pyridinamide salts derived from conductivity data revealed a lower degree of association in ion pairs with larger aryl substituted cations, which also correlates with their catalytic activity. Meanwhile, DOSY NMR results, which support this theory, showed a predominant cationic sandwich association in smaller anion–larger cation volume pairs. This is essential for maintaining a higher concentration of free nucleophilic anions in solution. The insights gathered in this study provide valuable guidelines for the future design of pyridinamide ion pair catalysts. Specifically, adjusting the size disparity between anion and cation within the ion pair could optimize the interplay between the degree of association and catalytic efficiency. This asymmetric association could open pathways for utilizing highly reactive free anions to activate substrates, that have previously been inaccessible to catalytic transformations.

The reactivity of the highly nucleophilic anions was quantified with the newly developed ionic strength-controlled benzhydrylium ion method. This method facilitates the comparison of pyridinamide salts with neutral nucleophilic catalysts, such as DMAP and TCAP. Pyridinamide ion pairs exceed the nucleophilic reactivity of the highly reactive neutral Lewis base TCAP by up to two orders of magnitude in DCM. Comparing the second-order rate constant k_2 values for pyridinamide anions reacting with cationic reference electrophiles at constant ionic strength $I = 1.0$ mM revealed the most nucleophilic anion **4** to be 90 times more reactive than TCAP. This newly developed methodology now allows for the investigation of pyridinamide anion reactivity toward a broader range of electrophiles, such as quinone methides^[8] or benzylidene malononitriles^[9], which were previously difficult to study due to the narrow concentration window needed to prevent ion association from influencing the nucleophilic activity of pyridinamide anions. With the newly gained control over the ion association through the regulation of ionic strength, it is now possible to access a broader range of electrophiles, including those requiring higher concentration due to lower absorbance. This advancement facilitates a more comprehensive study of the nucleophilicity of pyridinamide anions in low-polarity organic solvents.

The Brønsted basicity of pyridinamide salts has been quantified as pK_a values in water and water/organic solvent mixtures. The Lewis basicity of pyridinamide salts was quantum chemically calculated as methyl cation affinities (MCA). Therefore, the relative Lewis basicity towards Me^+ was calculated as the free reaction energy of an isodesmic transfer reaction with pyridine as reference system.

The superior reactivity of pyridinamide anions was demonstrated in the urethane benchmark reaction, where **4a** catalyzes the reaction seven times more efficiently than TCAP. Despite its high nucleophilicity and basicity, pyridinamide salt **4a** displayed only moderate catalytic activity in the Steglich acylation reaction. To investigate the cause of this reduced activity, the possibility of deactivation via protonation was explored. However, this hypothesis was ruled out through experiments with various auxiliary bases. Quantum chemical calculations focusing on the stabilization of the acylated pyridinium intermediate **12** might provide an explanation for the reduced catalytic activity of this strong Lewis base catalyst.^[10,11] To fully exploit their catalytic potential, it is recommended to employ pyridinamide salts primarily in addition reactions or rearrangement reactions, where acidic byproducts would not interfere with their catalytic effectiveness.

Given their enhanced reactivity, pyridinamide salts are excellent candidates for expanding their catalytic scope towards asymmetric catalysis. However, initial attempts to synthesize a chiral pyridinamide derivative posed significant challenges, particularly when adapting Vedejs' original synthesis for various 2-substituted pyridine derivatives. Computational studies offer a promising pathway to predict the reactivity and stereoselectivity of these derivatives, though further refinement of these methods is needed to enhance predictive accuracy.

In conclusion, we have established a solid analytical protocol for pyridinamide ion pairs in organic solvents of low polarity. The gained insights provide valuable guidelines for designing future ion pair catalysts with tailored association behaviors to enhance their reactivity. While the synthesis of chiral pyridinamide derivatives remains challenging, the potential of these catalysts in asymmetric catalysis warrants further investigation.

List of Abbreviations

κ	Conductivity ($\mu\text{S cm}^{-1}$)
λ_i	Limited (molar) ionic conductivity ($\text{S cm}^2 \text{mol}^{-1}$)
δ_i	Scaling factor for converting Λ_m into the respective λ_i
Λ_m	Specific molar conductivity ($\text{S cm}^2 \text{mol}^{-1}$)
B3LYP	Hybrid DFT method with Becke's three parameter exchange functional and Lee-Yang-Parr's correlation functional
calc.	calculated
CCDC	Cambridge Crystallographic data Centre
DMAP	Dimethylamino pyridine
DMSO	Dimethyl sulfoxide
DOSY	Diffusion-ordered spectroscopy
EI	Electron ionization
ESI	Electrospray Ionization
EtOAc	Ethyl acetate
EtOH	Ethanol
GC	Gas chromatography
h	Hour
H ₂ O	Water
HMPN	1,8-Bis(hexamethyltriaminophosphazenylnaphthalene
HPLC	High-performance liquid chromatography
HRMS	High resolution mass spectrometry
IR	Infrared
K_{ACA}	Anionic sandwich association constant (M^{-2})
K_{CAC}	Cationic sandwich association constant (M^{-2})
K_{IP}	1:1 Ion association constant (M^{-2})
LiTMP	Lithium tetramethylpiperidine
m.p.	Melting point
MCA	Methyl cation affinity
Me	Methyl
MeCN	Acetonitrile
MeOH	Methanol
MTBE	Methyl- <i>t</i> -butyl ether
NCI	Non-covalent interaction
NEt ₃	Triethylamine
NMR	Nuclear magnetic resonance spectroscopy
OMe	Methoxy
Ph	Phenyl
PPh ₄ BF ₄	Tetraphenylphosphonium tetrafluoroborate
PPY	4-pyrrolidinopyridine
PTC	Phase-transfer catalysis
R	Rest
RMSE	Root-mean-square-error
rt.	Room temperature
RTG	Research training group
TCAP	9-Azajulolidine
THF	Tetrahydrofuran
TMAJ	1,1,7,7-tetramethyl-9-azajulolidine
UV	Ultraviolet light
UV/Vis	Ultraviolet /visible light
vol _{an}	Anion volume
vol _{cat}	Cation volume

Academic Career and Education

- 2019/11 – 2024/12** *Ludwig-Maximilians-Universität München*
Ph.D. student with Prof. Dr. Hendrik Zipse on „Highly Reactive Pyridinamide Anions in Lewis Base Catalysis”
- 2023/04 – 2023/07** *Durham University, United Kingdom*
Research Stay aboard in the group of Prof. AnnMarie C. O’Donoghue
- 2021/04 – 2024/03** *Universität Regensburg*
Ph.D. student in the Research Training Group (RTG 2620) „Ion Pair Effects in Molecular Reactivity.”
- 2016/10 – 2019/03** *Technische University München*
Master of Science in Chemistry (M.Sc.), Thesis with Prof. Dr. Tanja Gulder
- 2013/10 – 2016/08** *Technische University München*
Bachelor of Science in Chemistry (B.Sc.), Thesis with Prof. Dr. Hubert A Gasteiger.
- 2005/09 – 2013/07** *Gymnasium Seligenthal, Landshut*
Allgemeine Hochschulreife (Abitur)
